2. Active fibroblastic proliferation is the chief feature of the central area. Intermingled therewith are fat-droplet spaces derived from the original adipose tissue, many of them being of large size from fusion of the contents of disintegrating fat cells. Scattered endothelial cells, lymphocytes, and "foamy" cells (fat- and lipoid-filled phagocytes) are present in small numbers.

3. In the outer zone of the lesion the most notable feature is the accumulation of the same foamy macrophages in large numbers throughout the adipose tissue. They occur in irregular groups and strands, separating the adipose tissue cells from one another, and are associated with slight degrees of fibrosis. The examination of frozen sections shows that they contain both neutral and cholesterol fat, taken up by them from disintegrating fat cells, many of which have their oil vacuoles filled by the products of cell degradation.

4. A few giant cells with "foamy" cytoplasm and up to six or eight nuclei are present here and there throughout the lesion.

5. The scanty gland acini present appear to be involved secondarily in the inflammatory process.

The appearances correspond to those which have been described in America under "traumatic fat necrosis." The lesion differs from the fat necrosis of pancreatitis in being of slow evolution, so that phagocytosis of fat-cell disintegration products and fibroblastic proliferation keep pace with cell destruction. The axillary glands show no pathological changes. The condition is met with in many different sites, but in the breast it is of special importance because of the danger of confounding it with scirrhous carcinoma.

The importance of traumatic fat necrosis from a clinical viewpoint lies in its simulation of carcinoma of the breast; in many of the published cases a radical operation has been carried out, and only later, on microscopic examination, has the true diagnosis been made. The recognition of the condition is therefore important and should be borne in mind, especially in what appears to be an early case of mammary cancer. In arriving at a diagnosis the traumatic nature of the lesion should be remembered, as injury seems to have been the starting point in most of the published cases. It is interesting to note that in three of the five cases of Lee and Adair[2] the disease developed after the giving of saline infusions into the breast. Although patients with carcinoma of the breast frequently state that they have had a knock or blow on the breast, or think the corset may have rubbed them, the exact nature and date of the injury is usually rather indefinite. In cases of fat necrosis, however, the exact trauma is clearly remembered.

The time interval between the injury and the development of the tumour varies from a week or two up to several years. The condition is usually met with during the fourth and fifth decade, and mostly in women with large and fat breasts. The tumour itself, although hard like a cancer, is better defined. The superficial fixity of the tumour to the skin exactly resembles that found in cancer, but deep fixity is not as a rule present. The axillary glands are not enlarged, though this does not help in the differential diagnosis from an early cancer. In a suspected case it will often be necessary to perform a local excision of the tumour for microscopic examination, since the mimicry of early mammary cancer is so close. If the condition is borne in mind, however, and only the lump removed, adequate treatment will have been carried out and an extensive operation obviated.

I am indebted to Professor M. J. Stewart for his advice in the preparation of this article, and for the report on the microscopic examination of the specimen in the case quoted.

SEVERE HAEMORRHAGE FROM THE RUPTURE OF A CORPUS LUTEUM CYST.

BY

D. LEVI, M.S.LOND., F.R.C.S.ENG.,

ASSISTANT SURGEON, INFANTS HOSPITAL, VINCENT SQUARE; SURGICAL REGISTRAR, ST. MARY'S HOSPITAL.

HAEMORRHAGE into the peritoneal cavity from a ruptured ovarian cyst is met with occasionally. Haemorrhage from a ruptured luteal cyst in a young woman, simulating an ectopic pregnancy, is a rare condition. Edward Moore[1] reviewed the literature in 1922 and could find only fourteen cases recorded, a list of which is given in his paper. Since that time records of several patients suffering from this condition have been published, notably in Germany by Kaboth,[2] Hesselberg,[3] Eick,[4] Schickele,[5] and others. But in the English[6] and American literature little mention has been made of this condition. It has been my good fortune to have been associated with three cases, descriptions of which are given below. As a ruptured ectopic pregnancy is closely simulated, a pre-operative diagnosis is difficult, and in this series the condition was not diagnosed before operation, and afterwards only when portions of the tissue removed had been sectioned and examined microscopically. By careful attention to the history, however, it should be possible to make a diagnosis. The most important points in the history are as follows.

The patient is a young woman, usually single; the average age in the following cases was 24. There is a history of a sudden attack of severe abdominal pain localized to the lower abdomen on the right or left side, depending probably on the ovary affected; this is accompanied by nausea, and occasionally by vomiting. The pain gradually passes off, and subsequently, following some strain producing increased intra-abdominal tension such as straining at stool, the patient has a feeling of faintness or actually does faint. The menstrual history is normal; there is no missed period, and the catastrophe bears no relation to the menstrual flow. On examination the patient is pallid, and sometimes restless and dyspnoeic. The pulse, generally rapid, thin, and running, may be slow. I have seen severe intra-abdominal haemorrhage with a pulse of 76. The temperature is usually subnormal, unless a considerable interval of time has elapsed between the

rupture of the cyst and the examination, when it may be raised. The abdomen moves with respiration, but is tender, especially on palpation of the lower quadrants; there is no rigidity. Per rectum, no mass is palpable, and there is absence of tenderness. Such a syndrome suggests a diagnosis of haemorrhage from a ruptured luteal cyst. The two conditions with which confusion is liable to occur are acute appendicitis and a ruptured ectopic pregnancy. The absence of epigastric pain, vomiting, hypogastric pain, and leucocytosis, combined with a flaccid abdomen, should exclude the former disease, and the absence of the history of a missed period and uterine haemorrhage, although not invalidating a diagnosis of ectopic pregnancy, renders it less probable.

Although the diagnosis may often remain tentative, the treatment must always be the same: immediate laparo-

FIG. 1.—Section of ovary, natural size. Corpus luteum cyst shown with a mass of blood clot in its cavity.

tomy, accompanied if necessary by a blood transfusion, since as soon as the peritoneum has been incised large quantities of blood escape. The operative treatment will not be considered in detail, but one or two points are worthy of further consideration. The abdomen should be opened in the mid-line below the umbilicus, the ovaries felt for, and the cystic one delivered. Should the condition be recognized, oophorectomy is contraindicated and the treatment of choice is to pass a mattress suture through the cyst wall. The blood in the peritoneal cavity should not be mopped out, but should be left, as it is quickly absorbed without producing adhesions, and acts as a slowly given blood transfusion.[6] The convalescence in the cases recorded below was speedy and uneventful. The recognition of this condition is important, and ovaries removed at operations for ectopic pregnancies should be subjected to careful microscopical investigation, especially if the virginity of the subject be called in question. Kaboth suggests that the presence of an ectopic ovum cannot be excluded unless serial sections of the tissue removed are cut and examined. This I do not think necessary; the large mass of blood surrounded by the crumpled yellow ring of luteal tissue forms an unmistakable picture macroscopically, and the histological appearances of a luteal cyst are characteristic and illustrated in Figure 2. It seems that trauma is a factor in causing rupture of the cyst and the consequent haemorrhage. There was a very definite history of this in two of the cases in the present series and also in many of those recorded in the literature. Another point worthy of emphasis is the absence of any definite relation to the menstrual cycle. The condition is more common than a perusal of the literature would lead one to suppose.

CASE I.

A single woman, aged 22, was admitted on March 4th, 1926, complaining of pain in the abdomen. At 9 o'clock that morning there had been an acute attack of abdominal pain localized to the lower abdomen, accompanied by nausea, but no vomiting. During the afternoon the patient fainted while straining at stool. The catamenia were regular. The rupture occurred four days before the period was due.

On examination the temperature was 97.8°, pulse 128, respirations 26. The patient looked ill and was pallid. There was generalized tenderness over the lower abdomen, but rigidity and distension were absent. Per rectum no tenderness or tumour was felt.

Operation (5 p.m.).—On opening the peritoneal cavity two to three pints of blood escaped. The bleeding was found to come from the right ovary, which was removed. The abdomen was closed. The patient made an uninterrupted recovery.

Pathological report on the tissue removed: Ruptured luteal cyst in a very oedematous ovary. There is a comparatively large vessel in the wall of the cyst which has probably given rise to the haemorrhage.

CASE II.

X, aged 31, was seen eighteen months ago. One afternoon, while straining at stool, the patient had a sudden attack of pain in the abdomen and collapsed. The menstrual history was irregular. The periods had been regular till five months before the date of illness, when there was a period of four months' amenorrhœa

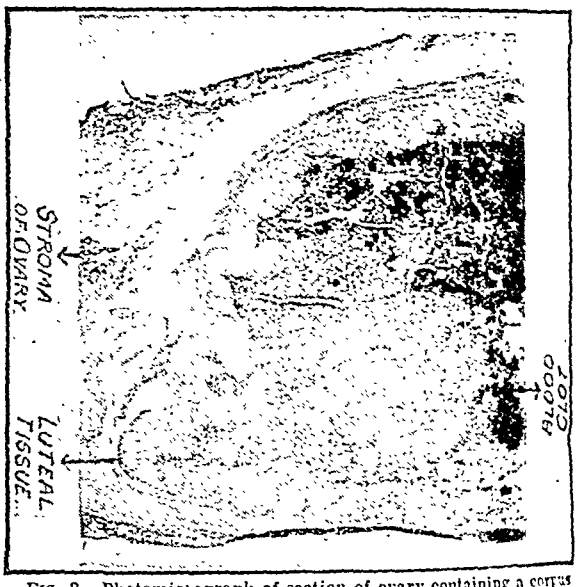

FIG. 2.—Photomicrograph of section of ovary containing a corpus luteum cyst. Yellow ring of luteal tissue surrounding blood clot is demonstrated.

followed by a loss on January 1st, 1926. The rupture occurred the second week in February.

On examination the patient looked ill and was blanched, the abdomen was distended and tender; pulse 140.

Operation.—On opening the peritoneal cavity a very large quantity of blood escaped. The right ovary was thought to be the site of an ectopic pregnancy, and was removed. The abdomen was closed without mopping out any blood.

The convalescence was uninterrupted. One year after the operation the abdomen was opened again for acute appendicitis. There were no adhesions present.

Pathological report on tissue removed: A ruptured luteal cyst of the ovary with haemorrhage around.

CASE III.

A single woman, aged 24, was admitted on March 13th, 1927, complaining of pain in the side. About midday on March 11th the patient had an attack of pain in the lower abdomen. The pain became more severe, and on the following day was accompanied by vomiting. The catamenia were regular. The rupture occurred ten days before the day the period should have started.

On examination the pulse was 120, the temperature 100, respirations 24. The patient was collapsed and waxy in appearance. The abdomen was tender all over, but especially in the iliac fossae; there was no rigidity. Per rectum there was tenderness, but no tumour could be felt.

Operation.—On opening the peritoneal cavity a large quantity of blood escaped. Some of the blood was sucked out with a suction pump, 29½ ounces being removed in this manner; about the same quantity was left in the abdomen. The left ovary was found to be bleeding and was removed. The patient made an uninterrupted recovery.

Pathological report on the tissue removed: A ruptured luteal cyst of the ovary with haemorrhage around.

I desire to express my thanks to the following members of the staff of St. Mary's Hospital: Professor Pannett, Mr. V. Z. Cope and Dr. W. Newcombe; also to Dr. Ling of Keighley, to whom I am indebted.

TREATMENT OF MIDDLE-EAR SUPPURATION.*

BY

HASSAN BEY SHAHEEN, M.R.C.S., L.R.C.P.,

AURAL SURGEON, KASR-EL-AINI HOSPITAL.

DISEASES of the middle ear, whether of the dry or suppurative type, tend to run a chronic course unless they are dealt with promptly and energetically. Adequate treatment can be ensured only if the patient is seen regularly; but in hospital practice, where patients are drawn from the working classes, one often finds that the patient's regular attendance can be secured only at the risk of his losing his work.

Dry conditions of the middle ear which have failed to derive benefit from catheterization and massage frequently respond to treatment by intravenous injection of colloid iodine; suppurative otitis media is, however, a far more serious and dangerous type of disease, and failure to treat it adequately has undoubtedly been responsible for a large number of operations on the temporal bone.

I have been able to cure many cases of chronic ear suppuration by the subcutaneous or intramuscular injection of milk boiled for three to ten minutes and injected at body heat. The treatment has two advantages: it is cheap, and it is within the province of the general practitioner. One injection is sometimes sufficient to stop discharge, though in cases with small granulations and a fetid discharge several injections may be necessary. The injections are often followed by severe general symptoms closely resembling those of an attack of influenza. Sometimes there are rigors, and vomiting may occur. Among patients observed under hospital conditions the reaction was found to begin within an hour or two of the injection, reaching its maximum in six to twelve hours, when often the temperature would rise to 103° or 104° F., and then return to normal in about twelve hours. Most of the effects passed off within twenty-four hours, but in view of the fact that there is sometimes pyrexia for two or three days, rest in bed should always be enforced.

When I first instituted this treatment I refrained from giving it to young children; with further experience I have been able to regulate the dosage, so that children may now submit to the treatment without suffering unduly. Treatment is contraindicated in patients with cardiac or renal disease, and the risk of anaphylaxis must always be considered and guarded against. The following is a short outline of a few of the cases treated by this method.

Case 1.—A girl, aged 6, had suffered from fetid discharge of the right ear for four years. She was given an injection of 1 c.cm., to which she had the ordinary general reaction. Two days later the discharge stopped completely. After five days a further 2 c.cm. were injected, again producing a general reaction. The condition appears to have cleared up and the ear is absolutely dry.

Case 2.—A man, aged 20, was admitted to hospital on June 11th, 1928, with a fetid discharge from the right ear, from which he had suffered for seven years. There was a posterior perforation, and small granulations were present; 5 c.cm. of milk were injected, and the temperature rose to 102°. On June 14th there was less discharge, but the fetor continued; 10 c.cm. were injected, and though there was again a general reaction, there was a diminution both in the amount of the discharge and in the fetor following. On June 20th another 10 c.cm. were injected and improvement was sustained. After similar injections on June 24th and July 1st, 4th, and 15th, the patient had rather more severe general reactions, but the discharge stopped. On July 28th the ear was still dry.

Case 3.—A male infant, aged 2, was brought to me with a post-operative sinus leading to the tympanic antrum, and with fetid discharge from the ear. A Schwartze operation had been performed, but during convalescence the patient fell into the Nile, and the operation wound became septic. Healing occurred, but the granulations were indolent and fetid discharge continued to appear from the external meatus. Following a milk injection of 1/2 c.cm. he had a general reaction, but there was a diminution of the discharge and fetor, and the granulations began to heal rapidly. After the third injection there was no discharge or odour from the middle ear.

These cases are in every way typical of a large number I have successfully treated by the method of milk injections. The immediate reaction of patients treated by this method is admittedly unpleasant, but I have no doubt that if its use becomes general there will follow a great reduction in the number of operations performed on the temporal bone. The radical mastoid operation will be resorted to only in cases of cholesteatoma or when intracranial complications are threatened.

* Abstract of a paper read before the Egyptian Branch of the British Medical Association, November 14th, 1928.

SLIPPED EPIPHYSIS OF THE HEAD OF THE FEMUR.

BY

JOHN J. ROBB, *M.C.*, M.B., F.R.C.S.ED.,

SURGEON CONSULTANT, COUNTY OF ZETLAND.

CONSIDERABLE interest has recently ranged around the problem of separation of the upper epiphysis of the femur, and particularly where the separation has taken place without the aid of trauma. Such a case recently came under my care, the features of which may be interesting to record.

A boy, aged 14 years, was admitted to hospital as an emergency case. He was in great distress, complaining of severe pain in the left hip-joint. Voluntary movement of the left leg was quite impossible, and even to touch the region of the hip-joint caused him to scream. As the boy lay on his back the thigh was slightly flexed and the foot everted. Over the greater trochanter there was quite a marked swelling, extremely tender to touch. The general disturbance was considerable; the boy looked ill; his pulse was 124 and temperature 100.2° F. An *x*-ray photograph of the hip-joint was taken, and it showed a true separation of the upper epiphysis of the femur, the head of the bone remaining in the acetabulum, the neck slipping proximally.

The history of this case prior to coming to hospital is that for some five to six months the boy seemed off colour. His appetite had diminished, and he appeared less energetic than was usual. Five weeks previous to my seeing him he commenced to complain of an aching pain in the left hip-joint, which came and went with the degree of rest he gave it. Occasionally the pain caused him to limp. At midday of the day of admission to hospital he was standing talking with his brother when something suddenly happened to his left hip-joint which caused him to drop upon the ground. From that moment he was unable to move the limb, and the pain he suffered was extreme. There is a very bad history of tuberculosis in his family. On his mother's side eight out of ten have died from the results of bone and joint tuberculosis.

The next features of interest were noticed during the course of his treatment.

The limb was placed in flexion, abducted by the aid of a Thomas splint, and 15 lb. extension applied by means of strapping, this following manipulation under a general anaesthetic. The result was good, and complete relief from pain was at once obtained. In two days the temperature and pulse subsided to normal, and at the end of five days the periarticular swelling and tenderness had gone. On the eighth day I measured the limb, and found it to be over-extended by fully half an inch. The weights were therefore reduced to 8 lb., and on that same night the pulse and temperature again rose. For three days I allowed the reduced weight extension to remain, and each day the swing in the pulse and temperature became greater. No pain, however, had returned. At this point the weights were increased to 12 lb., with the immediate effect of reducing the pulse and temperature to normal. During the next three weeks this amount of extension was allowed to remain, and no abnormal symptoms of any sort were present. To permit of more movement it was then decided to reduce the weight extension to 7 lb., but again disastrous results followed. The temperature and pulse immediately began to swing. After three days the 12 lb. were reapplied, the result being that symptoms again immediately subsided. Although active and voluntary movement was now encouraged, so long as this extension was maintained everything remained normal.

Two weeks later the extension and splinting were removed. Function was good, and all movements were performed without pain. Only in abduction was there some limitation of movement. In spite of this, however, from the moment extension was removed the pulse and temperature again began to swing—the pulse from 80 in the morning to 110 at night, and the temperature from 98° in the morning to 100° at night. After waiting for one week to see if these would subside, and failing to get such a result, it was decided to apply a hip plaster in an abducted position. This was done, and in twelve hours everything returned to normal and has since remained normal.

The principal features of this case are mentioned chiefly because of their etiological significance. All history of

trauma is completely absent, the Wassermann reaction is negative, and, so far as can be ascertained, no endocrine disturbance exists. S. T. Irwin, at a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on December 7th, 1928, stated that tubercle was not a causal agent in separation of the upper epiphysis of the femur. In the case described, though it is at present impossible to be dogmatic as to the cause, it seems equally impossible to eliminate the tubercle bacillus as a factor. The strong family tendency to this infection, and the behaviour of the lesion under treatment, are factors too suggestive to be lightly set aside in considering the cause of the condition and its prognosis.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CARCINOMA OF LOWER END OF ILEUM.

THIS case seems worthy of record for the following reasons: (1) the rarity of carcinoma of the ileum; (2) the difficulty of accurate preoperative diagnosis; (3) the difficulty of deciding the nature of the tumour in the small intestine by the naked eye at the time of operation; (4) the apparent absence of recurrence following only local excision of the growth and lateral anastomosis.

History.—The patient, a man aged 45 years, was admitted to the Dunfermline and West Fife Hospital on May 3rd, 1926. For six months prior to admission he had been under observation suffering from indigestion and fullness in the epigastrium, worse after food. During this time he had been very constipated, his bowels only acting with purgatives. His general condition was deteriorating, and he had been losing weight steadily. About three months prior to admission he began to complain of pruritus ani. On several occasions he had been treated for "gastritis," but on none of these had he vomited or suffered acute abdominal pain.

Examination.—The patient was spare and in poor condition. His colour was slightly sallow, and his tongue covered with brown fur. His abdomen was slightly distended, and the abdominal muscles were soft and flabby. Palpation on several occasions revealed tenderness on deep pressure over the right iliac fossa, with maximum tenderness over McBurney's point. No thickening was felt in the right iliac region, and there was no epigastric tenderness. Percussion revealed no abnormality of the liver and spleen. A provisional diagnosis of chronic appendicitis with reflex dyspepsia was made.

Operation.—On May 4th, 1926, the abdomen was opened through a right rectal incision, displacing the rectus inwards. There was a small amount of free fluid in the abdomen. The appendix, foetal in type, and acutely kinked on itself, was removed. Palpation of the duodenum, liver, and gall-bladder revealed nothing abnormal, but within the terminal portion of the ileum, about 3½ in. from the ileo-caecal valve, was felt a round mass about the size of a walnut. The mass was apparently fixed to the posterior wall of the ileum, but there was no dimpling of the serous coat at the site of attachment. The ileum was opened longitudinally, over the site of the tumour, and a small sessile growth evaginated. The growth was excised locally, and the longitudinal incision on the ileum was closed in the transverse axis of the bowel. The whole ileo-caecal region was turned upwards, and the incision on the posterior aspect of ileum, to which the tumour had been attached, was sutured in a similar manner. This suturing narrowed the lumen of the ileum so much that a lateral anastomosis of the ileum to the caecum was made. The after-treatment was uneventful and the patient was discharged on May 14th, 1926.

Histological Examination.—Dr. J. W. Dawson, Royal College of Physicians Laboratory, Edinburgh, reported as follows: "Section shows the presence of a diffusely infiltrating small-celled carcinoma. Further sections show a very marked thickening of serosa and subserosa with tumour cells."

After-History.—On June 4th, 1926, the patient had put on 1 lb. in weight, his bowels moving more regularly than they did prior to operation; pruritus ani had disappeared. On January 18th, 1927, he was again examined. He was still gaining weight, the abdomen was slightly tumid, the liver was not enlarged, and there were no abdominal symptoms. He is now doing full work and has put on 1 st. in weight.

The rarity of carcinoma of the ileum is shown by the following figures from the *Encyclopaedia Medica*: of 1,148 cases of malignant disease of the intestine (large and small) 26 cases occurred in the ileum. W. J. Mayo, in 1912, reported that of 1,498 operations for carcinoma of the gastro-intestinal tract, only 5 were for carcinoma of the ileum. The difficulty of diagnosing the condition accurately before operation is well brought out by Bland-Sutton, who, in *Tumours, Innocent and Malignant*, writes: "Cancer of the ileum gives rise to no signs which render the localization of the disease a matter of certainty." He also draws attention to the difficulty of deciding the nature of the tumour at the time of operation. In this case the diagnosis of a chronic appendix with reflex dyspepsia was made prior to operation, and it was only after the appendix had been removed and the terminal ileum had been palpated that the growth was discovered. At the time of operation there was no evidence of enlarged ileo-caecal or other glands, and the tumour, though sessile and hard, was so well defined that one formed the impression that it was adenomatous. The after-history bears out McK. Craig of Mayo Clinic, who, reviewing 36 cases of cancer of the ileum, wrote that, "although resection of the bowel with associated glands is the operation of choice, yet anastomosis round the lesion results in a high percentage of longevity."

I am indebted to Dr. A. L. S. Tuke for his advice in this case during the operation.

J. M. BLACK, M.B., Ch.B., F.R.C.S.Ed.,
Honorary Surgeon, Dunfermline and West Fife Hospital.

PREGNANCY ASSOCIATED WITH DIABETES MELLITUS.

WITH reference to the hospital case reported by Dr. Shirley Smith and Mr. Roques in the *Journal* of January 12th (p. 66) the following details of a case treated in the ordinary course of a country general practice may be of interest.

A panel patient, aged 20, arrived at evening surgery on April 12th, 1927, having walked a distance of about a mile up a steep hill. She looked and complained of feeling acutely ill, and gave a history of polyuria, constipation, marked thirst, air-hunger, and rapid loss of weight. Up to five days previously she had been carrying on her duties as a domestic servant. She was sent to bed, and a specimen of urine obtained on the following morning was found to be loaded with sugar; the specific gravity was 1035, and Gerhardt's test was strongly positive.

She was put on a diet consisting mainly of boiled cabbage, butter, eggs, and fish, with as little carbohydrate as we could persuade her to take. On April 13th an injection of 20 units of insulin was given with apparently little benefit; this was followed on April 14th by one of 50 units, and on April 15th by 80 units, with marked improvement in the quantity of sugar excreted. On April 16th 95 units was given, when the urine became sugar-free and Gerhardt's test negative. For the next three days she received 60 units daily, but sugar reappeared, and this was followed by the daily administration of 80 units for five days, which again caused the sugar to disappear. At this stage she was admitted to hospital for examination of the blood sugar content, but insisted on returning home on the fourth day, before a complete test had been performed. From April 30th she had 60 units of insulin daily, and gained steadily in weight, the sugar being diminished in quantity and occasionally absent. The insulin was gradually reduced, and by October she had gained upwards of a stone in weight and was taking 30 units of insulin daily.

She married in February, 1928, and in August gave birth to an apparently healthy, full-time male infant. The morning sickness was troublesome, but otherwise the pregnancy was uneventful, as was also the labour, which lasted less than twelve hours. During the early part of her pregnancy she had 20 units of insulin daily, but this had to be increased to 45 units towards the end of pregnancy; this dose was continued for eighteen days after delivery, when some mild attacks of hypoglycaemia caused us to reduce it to 30 units daily. She nursed her child, as she had an abundant supply of milk, and continues in excellent health, though the sugar is seldom completely absent. Owing to some slight recent loss in weight she has now returned to taking 40 units daily.

This case shows:

1. The successful treatment of a severe diabetic patient in general practice.

2. Agreement with the suggestion of Dr. Shirley Smith and Mr. Roques that the dangers associated with pregnancy and labour in diabetic women no longer exist.

3. Like them we had to increase the amount of insulin during pregnancy.

4. We found no necessity to reduce the amount of insulin until eighteen days after delivery.

5. The successful treatment of this case without the aid of blood sugar estimations.

Chalford, Glos.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

EGYPTIAN BRANCH.

A MEETING of the Egyptian Branch was held at Kasr-el-Aini Hospital, Cairo, on November 9th, 1928, with Colonel H. C. L. HIME in the chair.

Middle-ear Suppuration.

Dr. HASSAN BEY SHAHEEN, *aural surgeon to the Kasr-el-Aini Hospital*, read a paper, of which an abstract appears in this issue at page 643, on the treatment of middle-ear suppuration by the subcutaneous or intramuscular injection of boiled milk. In the course of the discussion Dr. Shaheen *added that he had used the treatment with good results* in cases of ozaena, acute otitis media, Bell's palsy, and sinusitis. Dr. AZUIZ EL KATTAN, ophthalmic surgeon to Kasr-el-Aini Hospital, commented on the value of this treatment in ophthalmic practice.

Compression Myelitis.

Dr. A. G. BIGGAM showed a case of myelitis in a man, aged 35, resulting from a fall on to the buttocks from a camel. Immediately after the accident there was complete *paralysis in both lower limbs, sensation was widely* affected, and incontinence of the bowel and bladder was present. Motor power, however, had improved rapidly, so that on admission to hospital two months after the accident paresis could be detected only in the calf muscles. Sensation was still widely affected bilaterally in the areas supplied by the fifth lumbar nerve and all the sacral segments. An *x*-ray examination showed the presence of a compression fracture of the body of the first lumbar vertebra, especially in its anterior part. Lipiodol injected by cisternal puncture revealed no obstruction at the seat of the fracture.

Treatment of General Paralysis of the Insane.

Dr. Biggam also showed a case of general paralysis of the insane that had been treated with intravenous injections of typhoid vaccine, with a view to stimulating general reactions similar to those which occur after treatment by induced malaria. Following the first four injections there *was marked reaction, with rigors, sweating, and rise of* temperature to 103° and 104°; but after this no reaction occurred even with large doses of vaccine. The patient derived no benefit from the treatment. Four months later he was readmitted to hospital, and received an intravenous injection of 5 c.cm. of *blood from a patient suffering from* malaria. The first rigor occurred on the fifth day after injection, and parasites were found in the blood. The patient continued to have rigors at irregular intervals until, after the eleventh rigor, quinine was administered. Antisyphilitic treatment was then given, but the patient showed only slight benefit.

Major W. L. FORSYTH contributed a summary of cases of general paralysis treated by induced malaria in one of the county mental hospitals in England. His impression was that the treatment, though in no sense curative, was an advance on those hitherto employed. In a few cases the process of mental deterioration seemed to be retarded, and some patients were able to leave the institution to follow their original employment. In none of the more advanced cases was there any apparent benefit from the treatment. Induced malaria could easily be controlled by intravenous quinine, and the additional course of novarsenobillon given to certain patients appeared to have no advantage. It was disappointing to find that even in cases which improved there was no corresponding amelioration in the Wassermann reaction of the blood or cerebro-spinal fluid.

Therapeutic Use of Brain-flap.

Mr. A. K. HENRY, director of the surgical unit, Kasr-el-Aini Hospital, gave an account of the rare clinical phenomenon of brain-flap, or extensive movements of the brain, synchronous with respiration, which he had studied experimentally with Professor R. Heathcote. The con*dition was apparently* well known to Ambroise Paré, who made certain of his patients with penetrating wounds of the skull which he had treated with tampons expel blood or discharge from between the open dura and the brain by forcing them to breathe out against resistance. He thus used the expiratory or bulging phase of brain-flap in a brain the volume of which had been kept reduced by pressure. Mr. Henry expressed his indebtedness to Professor R. Dobbin, who had given him access to his collection of the writings of old medical authors. He also exhibited some drawings made by Professor Dobbin of an instrument used in 1564 by Paré for opening the skull, which embodied the principles of Souttar's instrument.

Reports of Societies.

URINARY ANTISEPTICS.

At a meeting of the Sections of Urology, Pathology, and Therapeutics of the Royal Society of Medicine on March 21st there was a special discussion on urinary antiseptics. Mr. SWIFT JOLY was in the chair.

Dr. W. LANGDON-BROWN briefly described how the urine might become infected. Many organisms had been grown from the urine, but only a few were of practical importance—*B. coli*, *B. proteus*, streptococci, staphylococci, gonococci, and the tubercle bacillus. The enormous preponderance of *B. coli* infections was shown in a casual collection of cases which he had made from literature: of 437 cases of cystitis 199 grew *B. coli*, 109 of them in pure culture, and of 218 cases of pyelitis 174 grew this organism, 156 *being pure cultures. The problem of sterilization revealed* special difficulties. Was it possible to use an antiseptic strong enough to be germicidal by the time it reached the urine, and yet would not damage the tissues through which it passed? Was it possible to keep the drug in contact *with the urine sufficiently long for it to exert this germi*cidal action? Speaking of intravenous therapy, he said that it was not claimed, even by some enthusiastic supporters of this method, that the benefits were solely due to the direct germicidal action of the injected drug. *Mercurochrome had been most widely used in this direction;* he quoted the experience of workers at the Mayo Clinic that it should be employed intravenously only if emergency demanded it, but that in cases of acute sepsis, when other measures had failed, it merited trial. For oral administration there were few drugs of equal reputation about which so much difference of opinion existed as hexamine. In acute cases it nearly always caused too much irritation to be tolerated, though after a vigorous course of alkalis it might be more successful. He generally gave hexamine now in conjunction with methylene blue, since it seemed much less irritating. Hexyl-resorcinol (caprokol) was the most recent addition to the long list of urinary antiseptics. Very strong claims had been made on its behalf, which, if justified, might be held to be a set-off against its almost prohibitive cost. Acid sodium phosphate was recommended by Hutchison as a method of increasing the acidity, on the ground that it was the natural acidifying agent of the urine; in giving it one must remember that only half of *it was absorbed, the rest being excreted in the urine.* Boric acid appeared to act as a weak antiseptic in both acid and alkaline urine. Copaiba and sandalwood oil sometimes relieved symptoms and diminished the number of organisms in a *B. coli* infection, but it was particularly *after gonococcal cystitis that they appeared to have most* effect. As for vaccines, his impression was that they had never succeeded in rendering the urine sterile, but they might help to reduce toxaemia; they seemed to be more effective in coliform than in coccal infections. Dr. Langdon-Brown finally stated certain questions for discussion.

Dr. CUTHBERT DUKES reported an analysis of 28 cases of catheter cystitis in which the value of urinary antiseptics had been tested. In this disease severe infections, primarily due to pyogenic cocci, ran a chronic course, but mild and uncomplicated cases recovered without treatment in from four to six weeks. The influence of hexyl-resorcinol (caprokol), hexamine, methylene blue, and alkalis on the progress of this type of cystitis had been judged by clinical evidence, by daily quantitative estimations of pus in the urine, and repeated bacteriological examinations. Of "

seven cases treated with hexyl-resorcinol (caprokol) one recovered in thirty days and another in twenty-five days, both mild infections with a good prospect of spontaneous recovery. The remaining five derived no benefit. Of the twelve cases treated with hexamine only one got better more quickly than anticipated, and the other eleven did not benefit in any way. Most of the hexamine patients regarded the treatment as a disagreeable experience, and complained of discomfort, especially when free formaldehyde was present in the urine. In the four cases treated with methylene blue there was no sign of any favourable influence on the progress of the disease. The best results were obtained in the five cases treated with alkalis; they did not exert any antiseptic action in the urine, but they made the patient more comfortable, and might perhaps tend to shorten the natural duration of cystitis. Until some definitely curative remedy had been established the best plan of treating catheter cystitis was to keep the patient on a non-stimulating diet, to give large quantities of water, and to maintain the alkalinity of the urine. This relieved the bladder symptoms and placed the patient in the most favourable position for his own natural recuperative powers to overcome the infection.

Dr. PHILIP HAMILL said that relatively few coccal cases of urinary infection fell to the lot of the ordinary physician; the coliform infections were more common. It must be the experience of them all that they really could not push hexamine and acidification in the early stages, because of the pain produced. He had tried cases on drinking-water alone, and had been satisfied that they cleared up no more slowly than under hexamine. The difficulty was to get the patient to drink when the urine was acid and when there was pain each time the bladder was emptied. It was the value of alkaline treatment that micturition could be rendered painless, and then the patient could accept the advice to drink freely. Methylene blue made the patient more comfortable, but did not appear to diminish the quantity of pus. Hexyl-resorcinol (caprokol) was expensive, but produced comfort fairly soon, and the attainment of comfort was a very important thing. The difficulty with some patients was to swallow capsules as large as those containing this preparation. Was it possible to give a drug which made the urine bactericidal? He described an experiment which suggested that hexyl-resorcinol made the urine strongly bactericidal to *Staphylococcus aureus*, but unfortunately not to the more common organism, *B. coli*.

Mr. F. A. G. JEANS said that the effect of hexamine on a tuberculous kidney was to make it worse. Urotropine was irritating to the kidneys unless something was given to counteract it. Dr. L. P. GARROD described experiments on the rate of growth in an acid and in an alkaline urine. They indicated that the urine must be made strongly acid in order to interfere with the growth of *B. coli*; this was very uncomfortable to the patient. Mr. F. R. FEILDEN had been much impressed by the value of flavine, which he had given continually for the past nine years. It was one of the most powerful urinary antiseptics known; a dilution of 1 in 3,000 was sufficient to inhibit the growth of gonococci. He gave it with alkali because he believed it to be rather more efficient in an alkaline medium. Dr. KINGSTON BARTON said that so long as the urine was alkaline hexamine was of practically no use. The only drug that would bring down the acidity was acid sodium phosphate. From the experience of one of his patients it seemed advisable to give hexamine, not in a big dose at night, but in smaller and more frequent doses as early in the day as possible. Mr. JOHN EVERIDGE said that hexamine was a most valuable drug, and had an additional value if given some time after acid sodium phosphate. Dr. GEORGE GRAHAM was sceptical about the good results of hexamine. They were affirmed by the clinicians, but there did not appear to be pathological evidence. He had never seen a case in which it seemed to do any good whatever. Dr. ELIZABETH LEPPER described certain cases in which she thought hexamine did good.

Mr. SWIFT JOLY, from the chair, remarked that there seemed to be practically no antiseptic of any value at all at the kidney level. The greater part of the work mentioned that evening had been done in cases with organisms flourishing in the bladder. If there was any infection of the kidney, especially a coccal infection, which had continued for more than a few months, it was likely to persist indefinitely, and in time become bilateral, and end by killing the patient.

Dr. LANGDON BROWN said that the discussion had amply borne out his contention that there were few drugs about which so much difference of opinion existed. There was really very little satisfactory evidence of a pathological sort as to the efficiency of the drugs in common use, yet there was clinical evidence that the patients could be made more comfortable by the use of the drugs.

Dr. CUTHBERT DUKES, also in reply, made it plain that his own remarks had had reference only to catheter cystitis. He deprecated massive doses of alkali, which had no real object.

THE DENTAL ASPECTS OF RADIUM TREATMENT.

AT the meeting of the Section of Odontology of the Royal Society of Medicine on March 25th, with Mr. GEORGE NORTHCROFT in the chair, Mr. CYRIL H. HOWKINS of Birmingham read a short paper on the dental aspects of radium treatment.

Mr. Howkins said that radium in dental applications might be utilized in two ways—either by burying the needle, or by holding it in proximity to the growth when direct insertion of it was not possible or was inadvisable. The preliminary measures which dental surgery could undertake to assist radium treatment in malignant disease occurring in or near the buccal cavity included the removal of teeth and general elimination of oral sepsis, the removal of metal fillings, crowns, and bridges, to prevent secondary radiations which might cause necrosis, the removal of sequestrum, and the provision of some apparatus to hold or limit the action of radium, of some form of obturator to replace lost tissues, and possibly of dental splints when there was considerable loss of bone. The main problem for the dental surgeon was to design, prepare, and insert appliances, on the one hand to hold the radium in position, and, on the other, to limit the action of the radium. In either case a consultation with the radiologist was necessary, with an examination of the parts concerned and the taking of impressions. In this way a knowledge of the condition was obtained, and some idea as to the probable form of treatment, the number, size, and position of the needles, and as to the advisability of extractions and treatment of any existing teeth. The decision as to extraction depended upon circumstances. Any doubtful teeth near the growth should be removed at once, but where there were firm sound teeth some distance away, and the gingival margins were clean, he had let them remain because they were of great assistance in retaining an applicator or protector. The impressions, which should be wide ones, were taken in any suitable [illegible] of Paris was preferable—and then the des[illegible] and protecting appliance had to be considered. An applicator to hold needles in the proximity of the growth was so arranged that the needles were about 12 to 15 mm. away, and protection was secured by means of lead to prevent the rays attacking healthy tissues. The needles were inserted into shallow grooves and fastened by thread or wire, or in some cases by hard wax. A detached needle might be lost, with unfortunate results from more than one point of view. The cutting of the grooves should be done in consultation with the radiologist, and the model of the appliance in wax submitted to him for any observations he might make. As the appliance might have to be worn for from two to fourteen days, some form of firm retention was necessary. For this purpose springs, bands on remaining teeth, and upper and lower plates with "blocks" in place of teeth had been used. The material employed might be vulcanite or some form of "base plate"; the lead to protect the parts not to be irradiated must be incorporated or firmly fixed to the material. As the appliances were movable they might be taken out and cleaned when necessary, and immediately reinserted. It was extraordinary how well the patients behaved and how they endured the discomfort. The results had so far proved most satisfactory, and radium treatment in selected cases had opened up a fresh channel in which the dental profession could exercise its ingenuity.

Reviews.

JANET ON GONORRHOEA.

DR. JULES JANET is the oldest and most experienced of all living authorities on the subject of gonorrhoea, and his recent work on the diagnosis and treatment of blennorrhagia[1] cannot fail to be of the greatest interest to all who are called upon to treat venereal disease. His book is essentially a personal one, giving the results of a lifelong study.

The first part is devoted to a general consideration of the subject of gonorrhoea, and furnishes a warning to all who may be inclined to treat this disease lightly and to discount its gravity and danger. The second part deals with diagnosis in men; in it the author insists that the doctor who treats the trouble himself must make a bacteriological examination, and for this reason he supplies a careful morphological and biological study of the gonococcus. Following this comes an account of treatment, starting with abortive treatment by means of argyrol, and continuing with an exposition of the method of lavage with which the name of Janet is so closely associated. In carrying this out he insists on the use of an exact technique, and remarks on the frequency with which the method is wrongly applied. In a later chapter dealing with treatment he utters a necessary note of warning on the limitations of instrumental treatment. Following the apathetic period of treatment before the war came a time when experts in venereal disease attempted to eradicate the gonococcus by means of numerous and ingenious instruments. The urethra was subjected to dilatations, ionization, cauterization, and suction, with in many cases disastrous results. The urethral mucosa is easily damaged, and too often as a result of much instrumentation a gonococcal infection was followed by a chronic traumatic lesion. While recognizing the value of some of these forms of treatment in special cases, Janet declaims against their general use. The third part of his book is devoted to gonorrhoea in women, a disease which is even less satisfactorily treated than male gonorrhoea. In this chapter Janet's chief message is that, on the whole, there is a general tendency to neglect focuses of infection in the region of Skene's tubules and Bartholin's glands.

Among the more interesting of the later chapters are those devoted to infections of both parties in marriage, and to the problem of the marriage of the male who has suffered from chronic gonorrhoea. In describing the former Janet points out that when both parties are infected an immunity is soon established. If, however, a third person has sexual connexion with either of the infected members an acute form of the disease is only too likely to result. Concerning the marriage of a patient who has suffered from chronic gonorrhoea in the past, he is inclined to adopt an optimistic attitude. During recent years many authorities have used the method of spermo-culture as a means of determining whether gonococci are still present. As a result of the investigations of a series of cases, such authorities as Guepin, Lebreton, and Barbillon have stated that as many as 80 per cent. of cases of chronic gonorrhoea show the presence of gonococci in the sperm, and are, therefore, potential carriers of the disease. Janet discusses these astonishingly gloomy results, and points out that if they are to be accepted without qualification it would mean that marriage with a man who had suffered in the past from chronic gonorrhoea would be so dangerous as to be prohibitive. In his experience, although the infection of a bride by her husband is unfortunately no rare event, such a disaster is not as common as the results of spermo-culture would indicate. From his own case-sheets he would estimate the frequency of infection at 3 per cent. rather than at 80. At the present time he sees no means of reducing still further this risk, for there does not exist any method of analysis which can give complete and immediate security to any girl who marries a man who has suffered in the past from a chronic gonococcal discharge. Even a negative spermo-culture furnishes no complete guarantee. At the end of the work is appended a bibliography which covers twenty-seven pages.

It is almost unnecessary to say that the publication of Janet's book is an event in the world of venereal literature. While there are many points on which younger venereologists will differ with him, it is impossible to set aside lightly the opinions of the doyen of experts in gonorrhoea.

MODERN NEUROLOGY.

IN *Recent Advances in Neurology*[2] Drs. W. RUSSELL BRAIN and E. B. STRAUSS have given a full and satisfactory account of current neurological practice and theory, more particularly from the point of view of British workers. They devote chapters to the circulation of the cerebro-spinal fluid, with notes on the work of Weed, and the use of lipiodol in the diagnosis of spinal block; to intracranial tumours, basing their classification on the well-known work of Cushing, Bailey, and Penfield, and describing the use of ventriculography and the interpretation of ventriculograms; to the visual pathway and its disturbances in intracranial lesions; to the intracranial regulation of the cerebral circulation; to posture and tonus, and the clinical application of the work of Sherrington, Magnus, and other physiologists on the static aspect of muscular activity; to the work of British neurologists, especially Walshe, on paraplegia and hemiplegia; to the cerebellum and the extrapyramidal system; and to miscellaneous therapeutic advances, including an account of the ketogenic treatment of epilepsy. The chapter on Pavlov's work, though interesting, is too brief, and might with advantage include a consideration of the work of Krasnogorski on the development of the conditioned reflexes in children. Perhaps an English translation of Pavlov's book on the activity of the cerebral hemispheres will be published in time to secure adequate discussion in a future edition. The authors give a good account of epidemic encephalitis and the neurotropic viruses, though these are large subjects and difficult to present in compact form. Under miscellaneous therapeutic advances the ketogenic treatment of epilepsy is well set out. Altogether Drs. Russell Brain and Strauss are to be congratulated on a thoroughly creditable presentation of a difficult subject, with a well-balanced discussion of opposing views.

A TEXTBOOK OF MEDICINE.

THE development of specialism in medical practice is reflected in the tendency to produce textbooks in which the writing of each section is entrusted to a separate author, the function of the editor being mainly to choose his contributors, in the first instance, and then to ensure uniformity of manner and freedom from overlapping and disproportion of parts. *A Textbook of Medicine*,[3] edited by Dr. J. J. CONYBEARE, has ten such contributors, whose aim appears to have been rather to give an account of knowledge gleaned from many sources, and of the general consensus of opinion regarding their allotted subject, than merely to record personal experience. In addition to the usual subjects treated in textbooks of medicine, this volume of nearly 1,000 pages includes sections on diseases of the skin, diseases of infants, the common cold, and examination for life insurance. Clinical methods and details of laboratory technique have, for the most part, been omitted, and physical signs (in the editor's opinion better learned at the bedside) are described only sketchily. Speaking generally, the subject matter is clearly presented, and due weight is given to recent work. On the other hand, though much of the classification adopted is orthodox, certain exceptions call for comment. Von Jaksch's anaemia, for example, is grouped with diseases of the ductless glands, and no mention is made of the abnormal red and white corpuscles which are among its diagnostic features. The diagnosis of tuberculosis of the mediastinal glands is

[3] *A Textbook of Medicine.* By Various Authors. Edited by J. J. Conybeare, M.C., M.D.Oxon., F.R.C.P. Edinburgh: E. and S. Livingstone. 1929. (Demy 8vo, pp. xiv – 976; 15 figures, 8 plates. 22s. 6d.)

inadequately described, no mention being made of D'Espine's sign. In the section on diseases of the kidney not enough account is given of nephrosis and haemorrhagic nephritis, and the mechanical factor in many cases of chronic pyelitis is insufficiently stressed. The author of the section on respiratory diseases seems to overrate the significance of foreign proteins in the etiology of asthma. It must, however, be emphasized that these criticisms concern points of detail only, and that the book as a whole is, in our opinion, sound and adequately representative of modern views. Dr. Conybeare has himself contributed a great part of the work, and has shown considerable skill as editor in linking up the various sections.

OPHTHALMOLOGY.

A NEW manual of ophthalmology, entitled *The Eye*,[4] has recently appeared from the pen of Dr. C. W. RUTHERFORD of Indianapolis. Its aim is to provide a textbook for the student of medicine and a reference work for the general practitioner. The whole of ophthalmology is gone through systematically, each separate organ of the eye being treated seriatim, and dealt with under the headings of anatomy, clinical examination, and diseases with their appropriate medical and surgical treatment. In the first three chapters the lids, the lacrymal apparatus, and the orbit are considered. A large amount of space is devoted to the various plastic procedures which may be required for one reason or another on the lids; in the section on the lacrymal apparatus repeated probing as a method of treatment is recommended, and when operation is decided upon, excision of the sac is considered the method of choice, it being suggested that drainage operations into the nasal cavity are inadvisable owing to the fear of a spread of infection. There follow sections on the conjunctiva, the cornea, and the sclerotic; two chapters on the ophthalmoscope and the visual fields are interpolated, after which the inner parts of the eye are dealt with—the uveal tract, the retina, intra-ocular tumours, the optic nerve, the vitreous, glaucoma, and the lens. The remainder of the book is occupied by a consideration of the extra-ocular and intra-ocular muscles and refraction, and it concludes with a note on industrial injuries, their compensation and simulation.

On the whole the book follows very closely orthodox lines, and the teaching is essentially safe and sound throughout; while in this way it performs its essential function, it leaves little room for the original or distinctive in its pages. We are inclined to think that its most useful sphere would be as a reference book for the general practitioner; in its pages he will obtain much useful information presented in an easily assimilable form, and he will be guided over many of the pitfalls which ophthalmological cases present in general practice. For the student of general medicine—in this country at least—the volume is too expensive when compared with the other manuals of equal merit which are available. For the ophthalmic specialist, on the other hand, it is not detailed or critical enough, and for his purposes some recent developments in ophthalmological technique (such as, for example, the slit-lamp) have not been fully noticed in its pages. Like most American textbooks, the volume is extremely well produced; it is clearly printed and illustrated throughout.

ETIOLOGY OF PEPTIC ULCER.

REDWITZ and FUSS's pathogenesis of peptic ulcer,[5] which forms the forty-second volume of the New German Surgery edited by Küttner, should prove a useful work of reference in all questions relating to the etiology of that disease. The authors have undertaken the laborious task of bringing together and classifying every factor that can be regarded as being of direct or accessory etiological significance, and this has involved an examination of all the recorded work done on the subject. They have scrutinized the whole of the literature up to the middle of the year 1927, and the publications referred to, more than three thousand in number, form the basis of the work.

In dealing with the numerous etiological factors concerned the authors state very fully and impartially the evidence pointing to the significance of each and any criticism that may be urged against its acceptance. They remark that the enormous amount of work which has hitherto been carried out on the subject of gastric ulcer has not led to the adoption of any generally accepted doctrine, but to various and often contradictory theories, and this has, apparently, been due in large measure to the tendency to seek for some single specific cause, applicable in all cases. Acceptance of the view that a number of factors, variously combined in different cases, are concerned in the etiology is likely to lead to greater unanimity, and an accurate knowledge of all contributory pathological conditions present in individual cases cannot but be of importance in determining the line of treatment. It is not enough to know that a gastric ulcer may take origin in a necrotic patch in the mucous membrane as the result of local arterial obstruction or bacterial or toxic action; of more practical importance is the recognition of the accessory factors which tend to render chronic the ulcer resulting from the primary defect. Inquiry has to be made as to the possible retention of the stomach contents; mechanical conditions leading to deformity of the organ, such as ptosis and stenosis; the presence of altered conditions of the blood, hindering healing of the ulcer, and general circulatory or nervous affections having a like effect; the presence of chronic diffuse gastritis; and the possibility of auto-intoxication from hepatic or renal disorders. Whether an actual local bacterial infection may cause the continuance of an ulcer is, the authors consider, an open question; but the presence of the ulcer itself is recognized as an accessory factor in chronicity, by exposing the subjacent tissue to the action of the gastric juice, and causing irregular secretion, spasm of the pylorus, and irritation of the muscle of the stomach. Finally, a possible hereditary or constitutional predisposition has to be taken into consideration. These and other factors are discussed at length in this book, which affords the means of obtaining a good grounding in a complicated subject.

PHYSICS FOR STUDENTS OF MEDICINE.

PROFESSOR SIDNEY RUSS has produced an attractive hand-book on *Physics for Medical Students*,[6] in which his purpose of presenting the subject with an eye to the student's future preoccupations has been well achieved. Each of the nine chapters deals concisely with one branch of physics, and while the physics of sound occupies only nine pages and that of magnetism only twelve, much more space is allotted to the consideration of such topics as mechanics and current electricity, as being more important in the medical curriculum. The mechanism of muscular action is described and illustrated; it is calculated, for example, that a 10 st. man exerts a pull of some 26 st. with his tendo Achillis in raising himself on his toes, knowledge with which the student will be the better able to apply himself to the treatment of fractures of the lower extremity. The style of the book is clear and free from unnecessary detail, although here and there one finds excursions into trigonometry. The principle of the microscope is dealt with, perhaps, rather too briefly—a few words about the oil-immersion lens and a reference to dark-ground microscopy might have been included. There is an account of blood spectra on page 121, in which it is stated that citrated blood is examined. Specimens for this purpose should, of course, be made up with distilled water, not citrate solution, citrated blood being opaque. A purist might also object to the statement on page 145 that "tubes of force" are "sometimes referred to as lines of force." The book is well printed and the illustrations, which are mainly line drawings, are excellent. On page 109 "distance of distant vision" should, no doubt, read "distance of distinct vision."

NOTES ON BOOKS.

MR. CHARLES FOX, who is lecturer in educational psychology at the University of Cambridge, has written a volume on *Practical Psychology*,[1] which will be found invaluable to students of education, for whom it is primarily intended. The author expresses the hope, also, that it may have a wider appeal, since although the material has a definite educational bias, it ought to be of use to others who are interested in the practical psychology of the higher mental processes from other standpoints. The course of work here presented has been given for some years to students of education in Cambridge University. All the tests are quantitative, as the course is meant for class use. The book would appear to fill a gap in the literature concerned with experimental psychology.

We are told by Professor WILBUR PARDON BOWEN that kinesiology is the science of bodily movement. The word is not to be found in the *Concise Oxford Dictionary*, and therefore this interpretation is not superfluous, even when *Applied Anatomy and Kinesiology*[2] has reached this, its fourth, edition. This book is doubtless intended principally for the use of teachers of gymnastics and so-called "physical jerks," for much of the information contained in it on anatomy and physiology, as well as many of the illustrations, are to be found in the standard textbooks of physiology or manuals of human anatomy. Nevertheless, there is much in the book to interest trained anatomists, and to remind them of the problems of combined muscular action, but we are surprised to find no reference to the important subject of muscular tone, on the strength and normality of which the maintenance of correct posture in the erect position so much depends. The American Posture League, of whose activities we hear from time to time, is much concerned in encouraging correct posture, and in recommending such appliances of everyday use—for example, chairs and desks—as will enable good posture to be maintained at the least expense of neuro-muscular force. The photographs showing the action of the superficial muscles in the performance of various athletic exercises, such as throwing, putting the shot, etc., are interesting, as well as those of some industrial occupations.

Though Dr. A. C. GARNETT intends his book on *Instinct and Personality*[3] to present and apply an original standpoint in psychology, he has striven to make it comprehensible to the reader who has no special knowledge of the subject with which it is concerned. The writer develops a "hormic" theory of life. He takes the view that the simplest form of living organism is inexplicable in terms of chemistry and physics, and that the process of evolution must be interpreted as a striving toward the individuality which is manifested most clearly in man's conscious nature. The conclusion is finally reached that before animate organisms appeared on this planet, horme, life-force, *élan vital*, or "urge" existed, in some form, in inanimate nature. "This is a stupendous conclusion," Dr. Garnett writes, "and when we remember that matter itself seems to be resolved into something of the nature of 'drive' and organization, it is but a step to the conclusion that even inanimate matter is the creation of what, from the standpoint of our limited experience, we can best describe as universal Horme." It is evident that much thought has been expended in the preparation of this volume, and the author has been quite successful in making his views clear to the educated reader.

We have received the three numbers of the English edition of *Messrs. E. Merck's Annual Report*[10] for 1928. This publication is now issued thrice yearly. The volumes contain reprints of a few short articles on special drugs, but consist chiefly of abstracts of literature relating to the action of drugs. Inspection of the references shows that the great majority are to work that appeared in 1926. The volumes form a very useful reference book for obtaining information about work that has been done recently on drugs, and particularly on new proprietary remedies. Some of the drugs of particular interest of which an account is given are ephedrine, plasmoquine (the new synthetic substitute for quinine), psicaine (the new synthetic local anaesthetic), and thallium acetate, a drug which is used as a depilatory in ringworm. These reports are issued free to members of the medical and pharmaceutical professions on application to the publishers (E. Merck, Chem. Fabrik, Darmstadt).

A second edition, long overdue—the first was published in 1922—of Dr. W. J. TURRELL's book on *The Principles of Electrotherapy and their Practical Application*[11] is now available. So much has been added, so much revised and rewritten, that it is almost a new book, rather than a second edition. Especial attention has been given to the high-frequency currents, the good results following on the treatment of pneumonia by diathermy, and to Jellinek's important work on the causes of death from high-voltage electricity. We reviewed very favourably the first edition, and have an equally good opinion of the second. The author is an original thinker and writer, and his book, in which his own opinions are very much in evidence, is on this account all the more valuable.

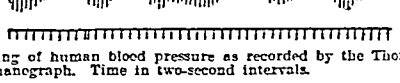
PREPARATIONS AND APPLIANCES.

AN APPARATUS FOR OBTAINING CONTINUOUS RECORDS OF HUMAN BLOOD PRESSURE.

MR. J. H. THOMPSON, B.Sc. (Department of Physiology, Middlesex Hospital Medical School), writes: Since my preliminary communication[1] appeared the apparatus for recording human blood pressure continuously has been considerably improved in several directions. It is now possible to obtain records for unlimited periods of time without causing the least discomfort to the subject. The instrument is sufficiently sensitive to record accurately the most rapid fluctuations in blood pressure, and is designed to indicate on the recording surface variations of blood pressure in terms of millimetres of mercury. By means of a simple device the results can be magnified or diminished. The improved apparatus consists of a water manometer, one limb of which is of greater diameter than the other, with a reservoir into which the fluid can be emptied at the conclusion of an experiment. A specially constructed glass float already described carries the recording pointer.

In the earlier experiments the apparatus was connected with a sphygmomanometer bag. After a period of five minutes the venous congestion was considerable and much discomfort was experienced by the subject; it was impossible, therefore, to record continuously for a longer time than ten minutes. A special armlet has been devised whereby these untoward effects are eliminated. It consists of two wide strips of aluminium joined by a hinge on one side and by a "throw-over" catch on the other. One strip is perforated by a piece of narrow rubber pressure tubing which is connected to a small rubber bag, about two inches square, resting within the concavity of the metal band. The bag is connected to a T-piece, one limb of which leads to the manometer and the other to a small metal hand pump. The other strip is also perforated with a metal screw-rod, to which is attached a small metal plate suitably padded. The armlet is placed over the elbow so that the bag rests upon the brachial artery, the catch is secured, and the plate screwed until the whole armlet is firmly fixed in position. The bag is then inflated and a record taken. It is found that by using this apparatus no venous congestion occurs, and the veins on the lateral and posterior aspects of the arm (which are not compressed) are sufficient to maintain an adequate venous return. With the arm comfortably supported, subjects are able to give continuous records for over an hour without any discomfort.



Tracing of human blood pressure as recorded by the Thompson sphygmanograph. Time in two-second intervals.

Several precautions must be taken in using the apparatus. It is advisable to place a three-way tap between the inflator and the apparatus, since the slightest leak in the apparatus results in a slow persistent fall on the record. It is almost impossible to obtain inflators which do not leak. It is therefore best to interpolate a three-way tap, so that after the inflation has been done the pump can be eliminated from the pressure system. It is also important that the subject should keep still. It will be readily understood that slight movements of the biceps muscle will cause rises of pressure within the bag. These are easily discriminated by their sharp outline and rapid return to the original base line. But they are apt to spoil a good tracing, and in this laboratory the practice has always been to request the subject to remain perfectly quiet.

It is obviously of value, however, to be able to record blood pressure during movement on the part of the subject—for example, during exercise. In order to make this practicable another armlet has been made for the wrist. It is elliptical in shape and the bag is long and very narrow, to fit the groove between the radius and the flexor carpi radialis tendon. Otherwise its structure is comparable to the brachial armlet. Experiments performed with this wristlet indicate that variations in blood pressure can be recorded equally well, excepting that the individual heart beats are not so large. But the great advantage is that the subject can move about and actually exercise the arm without any mechanical disturbance of the pressure system.

This sphygmanograph is now made in portable form by W. Pitman, c.o. this laboratory. Patents have been applied for.

SATURDAY, APRIL 6TH, 1929.

THE CHANGED OUTLOOK ON CARDIAC DISEASE.

MANY of those engaged to-day in general practice have a vague feeling that modern research in cardiology, so especially associated with the names of James Mackenzie and Thomas Lewis, has largely revolutionized the teaching about heart disease to which they were accustomed in their student days. To some extent this is true. There has, indeed, been an addition to our knowledge, and, if we may so express it, a subtraction from it. Owing largely to the help of the electro-cardiograph, a knowledge of the contraction of the various chambers of the heart has been obtained which did not exist formerly. Consequently, some order has been introduced into the chaos of cardiac arrhythmias which previously were so jumbled up together and inadequately differentiated that neither the meaning of sinus arrhythmia, which is hardly pathological, nor the relative unimportance of many kinds of extra-systole was in the least understood. Again, though auricular fibrillation may have been dimly recognized under the form of the "mitral pulse" or "delirium cordis," its essential significance was by no means realized. Digitalis, doubtless, was given in such cases, and given with success, yet no one knew that this success was due to the introduction by the drug of a partial heart-block. Though at first it required the string galvanometer to make scientific distinctions between the various arrhythmias, fortunately they can now in most instances be recognized clinically without instrumental methods.

On the other hand, we must subtract from some of our previous knowledge, in particular that which concerned itself with murmurs, for their significance has been much diminished by modern teaching. In medicine, as in religion and politics, there is always a tendency to rush to extremes when any new doctrine is being inculcated, so that some disciples of the new cardiology have been inclined to convey the impression that most murmurs have no importance at all. Certainly in the past a disproportionate amount of study was devoted to murmurs, and whereas previously their meaning was overestimated, it now runs the risk of being unduly minimized. Murmurs are easy to recognize and easy to teach upon, which may account for the great amount of time and learning which has been bestowed upon their origin and transmission from a purely mechanical and acoustic point of view. But the essential change brought about by modern cardiac research is in directing attention to the primary importance of the heart muscle. It must not be supposed that our predecessors were not fully alive to the importance of the heart muscle; thus Laennec, the discoverer of mediate auscultation, spoke of the condition of the myocardium as "the key to cardiac pathology," while William Stokes in 1834 said that no matter what the heart affection may be, "its symptoms mainly depend on the strength or the weakness, the irritability or the paralysis, the anatomic health or disease of the cardiac muscle." But teachers, not unnaturally, have followed the line of least resistance, and have found it easier to give instruction about murmurs, which are there for everyone to hear, than about the myocardium, which, until it is grossly degenerated, may give no evidence of impairment, and may, indeed, cause sudden death in persons who have shown no signs or obvious symptoms of heart disease.

Apical systolic murmurs are now generally believed to be due rather to weakness of the myocardium, perhaps only temporary, which prevents the coaptation of the mitral valve, than to the presence of an organic valvular lesion. We realize now that though the presystolic murmurs of mitral stenosis and the diastolic murmurs of aortic regurgitation indicate the existence of a definite valvular lesion, they provide no definite knowledge as to the strength of the myocardium, and only to a minor extent give a clue to the cause of the lesion. But in any cardiac affection a knowledge of the cause is supremely important, indeed, as the late Professor Huchard used somewhat paradoxically to say, in the case of valvular lesions it is more helpful to know the cause of the lesion than which valve is affected. A structural lesion due to rheumatic fever and its congeners is likely to remain stationary, a fact which may afford ground for a favourable prognosis; on the other hand, a lesion due to syphilis or arterio-sclerosis is likely to be progressive, so that the outlook must necessarily be more unfavourable.

It may be that, apart from the very important knowledge we have gained of cardiac arrhythmias, our diagnosis of cardiac affections has not greatly advanced in the past generation, nor, when once the heart has broken down, have our methods of treatment greatly improved, except in the more scientific administration of digitalis. But considerable advance has been made in the prognosis of cardiac affections. More and more it has come to be realized that in every case of heart disease a knowledge of prognosis is vital. It is not merely a question of estimating the patient's expectation of life, but how effective his life may be made, what sort of occupation he can fill, and what kind of activities, whether physical or intellectual, he can wisely be allowed to follow. Our power to answer questions such as these has certainly much increased of late years. This advance has been brought about largely by the attention that has been directed to the estimation of the strength or weakness of the heart muscle by careful study of the patient's symptoms, and, in particular, by observation of the cardiac response to effort. From a purely prognostic point of view it is recognized that murmurs and their varying changes have much less value than they were thought to have a generation ago.

In former days disease of the heart was held to spell if not the likelihood of sudden death, at least the certainty of a more or less invalid life. We now know that there is an immense difference between an invalid life and a life of restricted activity. There is no question that many patients with heart disease are now allowed, and wisely allowed, to do much more

than they would have been in the past. The modern doctor, armed with additional and more securely based knowledge, unlike his predecessor, endeavours to follow the advice of Plato, who said that the patient should be prevented from nursing his disease to the neglect of his ordinary calling.

THE LOCAL GOVERNMENT ACT.

THE Local Government Bill, 1929, has now received the Royal Assent, and become an Act of Parliament. The corresponding Scottish bill will achieve the same status shortly after Parliament resumes session. Each of these Acts will constitute a far-reaching reformation of local government, and each effects a measure of reform in public health administration not less than that accomplished by the most important previous Acts dealing with these matters. The measure of practical success to be achieved by these reforms depends now upon the methods and efficiency of their administration. This is in the hands of the Ministry of Health and of the councils of county boroughs and of counties in England and Wales, and in those of the corresponding bodies in Scotland. The Scottish Act is even more far-reaching than the English, inasmuch as it affects the administration of education, which the English Act scarcely touches, and alters more widely than that Act the areas of local government.

Though very few of the actual amendments placed on the paper in order to carry out the policy of the British Medical Association have actually been embodied in the Act, the pressure exercised has not been without its effect. The clause empowering the councils of counties and of county boroughs to exercise transferred functions through the appropriate Public Health Acts instead of through the Poor Law has been materially strengthened so as to make it clear that the former method is to be adopted wherever possible. A Ministerial declaration in favour of the co-option on committees, in most cases, of persons of suitable status and experience not themselves members of the appointing councils has been obtained; and it is to be expected that suggestions on these lines will be contained in the circular which it will now be the duty of the Ministry of Health to issue to local government authorities. Owing largely to the efficient and persistent help of Lord Dawson, a new requirement has been secured that councils, before taking action as to the provision of hospital accommodation or deciding on the uses to which it shall be put, shall make such arrangements as they think desirable to consult any body within their area which they consider representative of the governing bodies and of the medical staffs of local voluntary hospitals. None of these things goes as far as the Association would have wished, but each is an important step in the direction desired; and it is a matter of great moment that in every area the medical profession, through the appropriate Division or Branch of the Association, should exert its influence in order to bring about suitable administrative action.

The immediate action required from the councils concerned is the preparation of an administrative scheme for performing the functions transferred to them from the Poor Law guardians. Each council must submit such a scheme to the Minister of Health for his approval before the end of September next; and, on submission, must advertise locally the fact that this has been done and that representations thereon may be made to the Minister within a period of four weeks. Schemes sanctioned will become operative on April 1st, 1930. Draft schemes are already being prepared in a number of areas, and it is clear that any action taken by the medical profession should not be delayed until the publication of a scheme, but should begin at as early a date as is possible. In order to assist in the effective direction of such action the Council of the Association is issuing to each Branch and Division, to medical officers of health, and to medical members of local government authorities and their committees an explanatory memorandum directing attention to the most important points. This memorandum is printed in this week's *Supplement* (p. 77), and the earnest attention of every member of the Association is requested thereto. The three points referred to above—action wherever possible through the appropriate committees and Acts rather than through the Poor Law and the Public Assistance Committee, the co-option of members of the medical profession wherever this can be secured, and the formation of a really representative consultative hospital committee—are those in reference to which the speediest action and greatest pressure are needed. The position and status of transferred district medical officers is also a matter of the very greatest importance, not only to those officers themselves, but to the whole profession in relation to domiciliary services. All these questions have their peculiar difficulties, and it is likely that with regard to some of them it may be necessary to issue some supplementary memorandums of information and advice. Meanwhile it is impossible to overemphasize the importance of the situation and its potentialities; and it is necessary to urge that all concerned in the development of public health services and the relation of the medical profession thereto should realize this, and should, after full consideration, take early and appropriate action.

DOCTOR AND PATIENT.

THERE are many things in the art of medicine which can be learnt by experience only. Nevertheless, the attempt to point out to the senior student or newly qualified practitioner the direction in which some of these things lie, to warn him against mistakes into which he may easily fall, and to help him towards an adjustment of his attitude in relation to various kinds of personality in his prospective patients, is a task well worth doing. Some such task as this has been essayed in a series of lectures delivered within the last few years before students of the Harvard Medical School, and these lectures are now published in a volume entitled *Physician and Patient*,[1] under the editorship of Dr. L. Eugene Emerson. The theme of the lectures is, in general, that it is the patient as well as the disease that requires treatment, and that the patient's mind must be taken into account as well as his body. It is probably the case that the course of training in a medical school, even the clinical instruction and observation in a large hospital, with their necessary insistence on the basic sciences, on laboratory methods, on instrumental aids, and on the observation of physical signs, do not emphasize sufficiently the human relations between doctor and patient and the need for psychological insight and sympathy. In actual practice, of course, these are all-important, even though the fact be recognized that the doctor can never know too much about his patient's physical condition. Unless a student has a character or temperament which permits of the [illegible] development of such relationship and insight [illegible] and unfitted for most branches of the medical [illegible] unless a practitioner does actually cultivate [illegible]

[1] *Physician and Patient: Personal Care.* Edited by [illegible]. Cambridge, Mass.: Harvard University Press. 1929. (5½ × 8, pp. viii + 244. 11s.

never be really successful in his calling. There can be no doubt that these things, along with some others connected with the daily practice of his profession which are not often included in his educational course, ought to be impressed upon the student. Most of the articles in the volume under review must certainly have been, when they were delivered as discourses to a suitable audience, valuable contributions to this end. Each of them contains some noteworthy saying, some wise observation, some narration of interesting and instructive incident. That, however, which may well be said once a year, or even once in a university term, in its appropriate place, will not necessarily be useful, or even tolerable, when read nine times over within a few hours, even if the form be modified. The collection of these lectures in one volume does not make a good book for whatever class of reader it is intended. The last three of the nine essays are somewhat different in character from the rest, and are less good in themselves. They are all by Dr. Alfred Worcester, and are on the care of the aged, the care of the dying, and the attention to personality in sex hygiene. The fact that in the medical care of the very old and of the dying a time comes when all attempts at curative treatment should be abandoned, and attention should be directed solely to comforting and sustaining the patient, in spite of the fact that his friends may still be clamouring for active therapeutic measures with a view to possible recovery or prolongation of life, and that this constitutes a real difficulty at times for the practitioner, is worth setting down; but beyond this the three essays do not seem to contain much of value. To advocate that the treatment of senescence should be elevated into a specialty, and that the absence of a library of books on the subject is a disgrace to the profession, shows a sad lack of judgement and of a sense of proportion. It is to be hoped, too, that the following statement is not true of America, as it is certainly untrue of Great Britain: "The advance of medical science is now furthered only by the discoveries of the specialists. Dazzled by the brilliancy of these, general practitioners have ceased communicating to the profession even the results of their experience. Consequently in their particular fields neither medical science nor the art of practice advances." On the contrary, the advance, surely, is so great as to justify the conclusion of Dr. Thayer's lecture or parable entitled "The Medical Education of Jones: by Smith." "'Doctor,' said one of the boys, 'Have you read *Arrowsmith*?' 'No,' said Jones, 'but I will.' He read it, lay back in his chair, and laughed. 'By Jove,' said he, 'I might almost have written that myself twenty-seven years ago.'"

CREMATION IN ENGLAND.

It is probable that the general adoption of cremation is, to some extent, hampered by the existence of a definite opposition to this method of disposing of the dead; but the greatest obstacle would appear to be a widespread reluctance to think of the matter at all. Many persons, it is true, are prepared to discuss the desirability of cremation, in the abstract; some will even discuss it in concrete terms, so long as present company is excepted. It is, however, a big step from an academic acquiescence in cremation to a willingness and a capacity to leave explicit instructions about the disposal of one's own dead body, a bigger step than most people are at present prepared to take. Nevertheless the number of cremations carried out in the United Kingdom is increasing, though very slowly, and new crematoriums are being established. The council of the Cremation Society of England, in its annual report for 1928, states that in that year the total number of cremations carried out in Great Britain was 3,456, a figure representing an increase of 5.24 per cent. over that for 1927, and of nearly 30 per cent. over the last five years' average. There are now twenty crematoriums in the British Islands, this number including the new buildings at Ipswich and Bristol, one in course of construction at Guernsey, and another at Edinburgh. The provision of crematoriums is being considered by various local authorities and burial boards throughout the country, and though their schemes may not mature immediately the council holds that the very fact that the question is being seriously discussed is evidence that cremation is coming to be regarded as the only practical solution of the problem which arises from the rapidly diminishing space available for burial purposes in and near populous centres. During the year useful propaganda has been carried out at a number of health week exhibitions in co-operation with the Central Council of Health Education, and numerous lectures on behalf of the society have been given to organizations such as the Women's Co-operative and Labour Guilds, adult institutes, and Young People's Fellowship meetings. Though no immediate results are expected from these methods of propaganda, which in the main reach the less well-to-do classes, it is hoped that the education of the masses of the public may help to bring about an alteration of the existing law, or enable the society, by some form of industrial insurance, to bring cremation within the reach of the poorer classes.

THE BROAD TAPEWORM.

THE broad tapeworm of man, *Diphyllobothrium latum*, which is not uncommon in the Scandinavian districts of Europe, has in recent years become naturalized in the Great Lake districts of Canada and the United States owing to immigration of these northern peoples. In some of the lakes a high percentage of fish are now infected, and as these are used extensively for food the dangers of a heavy human infestation would be considerable were it not for the fact that the fish are almost invariably cooked before being eaten. The infection can only be continued through the contamination of the water by the faeces of fish-eating mammals, of which man is the most important. Vergeat,[1] however, has recently found that the fish in certain lakes which have a very small human population on their shores are heavily infected, and the fact that innumerable dogs abound—and it is well known that dogs, cats, and other carnivores, including bears, can harbour the adult parasite—suggests that they are the reservoirs from which the fish become infected. The parasite is long-lived and enormously prolific, producing several millions of eggs daily, and a single person can therefore infect a whole lake and keep it infected for a very considerable time. Moreover, the importance of a single infected human host is increased by the fact that fish, especially pike, can live for long periods, and so maintain the potential infectiousness of a region for years after the departure of the original source. Information as to the longevity of the parasite is in part based on the records obtained from American immigrants before it was known that the parasite had become naturalized; and these must therefore be regarded with some suspicion. However, Professor R. T. Leiper[2] records an experimental infection in himself which persisted for over five years without exhibiting any definite symptoms during most of this time. A remarkable feature of this case was the complete absence of segments in the stool, although eggs were always found when microscopic search was made. This fact is of some importance, as the presence of a tapeworm is always suspected in the first place from the passage of segments. If these are absent the parasite may exist for years without either the patient or his medical attendant suspecting its existence, and so perpetuate the possibilities of infecting the fish in any lake into which the

[1] *Journ. Amer. Med. Assoc.*, February 23rd, 1929.
[2] *Journal of Helminthology*, December, 1928.

faeces may pass. In addition to harbouring the adult tapeworm, man, especially in the East, may also harbour the larval stages of several related species which live as adults in the dog and cat. These larvae occur, among other animals, in frogs, and the parasite is acquired by its definitive host eating the frog. (It has recently been shown by Professor Faust that they will not develop in man when the larva is swallowed.) In human beings the larval stage is generally known as *Sparganum mansoni*, after Sir Patrick Manson, who discovered them in Amoy in 1882. It has always been supposed that man becomes infected by swallowing the first intermediate host—a species of *Cyclops* or water-flea—and consequently functions as a second intermediary. But Dr. Faust suggests another explanation. In some of his cases there was a history of an abscess, to which the patient, after the manner of the country, had applied "split" frogs: a similar practice is in vogue in Indo-China, where ocular sparganosis is common, to relieve severe conjunctivitis. The theory that the larvae, which are present in nearly every frog, actively migrate from the *poultice to the patient is an obvious one, and has actually* been proved to be possible by Dr. Faust. Spargana were placed on the orbit of a dog, and observed to penetrate the conjunctival membranes and cause the development of a severe inflammatory process. Other experiments indicated that the larvae, when introduced aseptically into the musculature, were able to multiply asexually over a period of several months—a phenomenon which may explain the rare and peculiar parasite known as *Sparganum proliferum* very occasionally found in human beings.

A TYPHOID CARRIER ON A SHIP.

In 1927 three separate outbreaks of typhoid fever occurred on a passenger ship making round trips to South America, each of two months' duration. The first outbreak occurred in January, with eight cases, the second in July, with *eleven cases, and the third at the end of the year, with* ten cases. It was decided that as there had been no typhoid in the other ships of the line the source of the outbreak must be looked for in the ship itself or in the members of her crew. An investigation was undertaken accordingly by Dr. J. E. Dinger of Amsterdam, for whom a laboratory, with all necessary equipment and subsidiary preparation and washing-up rooms, was built on board the ship. From his account[1] it would appear that his chief difficulties were occasioned by the constant changes of temperature during the voyage and by the movements of the ship. The scope of his investigation was fortunately limited by the discovery that, though the water supply was common to every part of the ship, all the cases recorded had been fed from the second-class pantry. Water was thus excluded as a cause of the outbreak, and the problem became that of discovering the carrier or carriers. Of the 163 persons on board who had served during all the epidemics, six gave a positive Widal reaction, but none had typhoid bacilli in the stools. Examination was then made of the stools and urine of those who in any of the voyages had come into relation with the second- or third-class passengers, or with the food of those classes. In all, the stools and urines of 256 persons were examined, and a leading hand in the engine room was found to be excreting typhoid bacilli. The first cases of the January outbreak had occurred in the engine room, and this carrier, it was found, had shared a cabin with the very first of those cases. Which of the two infected the other could not be decided. The author does not record whether this carrier gave any history of a previous attack of typhoid fever, but it is evident that he gave a negative Widal reaction. The fact that he had nothing to do with handing the food for the passengers or crew may explain the intermittence of the epidemics. After he was segregated and eventually disembarked there was no further outbreak of typhoid fever on board. Dr. Dinger, as an additional precaution, tightened up the food-handling regulations of the ship, and inoculated the whole of the crew against typhoid. He holds that protective inoculation should be carried out from time to time among the crews of all ships entering tropical harbours.

[1] *Archiv für Schiffs- und Tropen-Hygiene*, January, 1929, p. 37.

"THE HEALTH OF THE NATION."

In our review of Dr. F. E. Fremantle's book on *The Health of the Nation* in the *Journal of* October 15th, 1927 (p. 688), we expressed the opinion that future editions were certain to be required, and suggested to the author some points for notice when revision was needed. It is a pleasure to discover that a second edition[1] has already been necessary, and that some of these suggestions have been adopted. The second edition appears in the handy form of a volume of what the publishers have called the Westminster Library. A few small and quite unnecessary references of a party political character have been deleted. The paragraphs dealing with the registration of deaths now describe the new and not the old procedure, which was obsolete even at the time of publication of the first edition. The effects of the National Health Insurance Act, 1928, are described or noted, and the main relevant effects of the Local Government Bill, 1929, now an Act of Parliament, are referred to. Two small errors in this revision have caught our eye. On page 149 the new short paragraph concerning seamen's insurance is misleading. The great majority of seamen, like other employed persons, have been within the scheme of national health insurance from the beginning. Clause 20 of the Act of 1928 merely extends the scheme to those seamen who are paid, not by wages, but by a share in the profits of the adventure. This is a small but important class who were formerly denied the insurance benefits in so far as they were not strictly employed within the meaning of the Acts. On page 152 a further 3,000 should have been added to the membership of the British Medical Association there given. We are still of the opinion, even more emphatically than when we stated it in our earlier notice, that the scheme of the book almost necessitates a somewhat expanded description of additional treatment benefits (especially dental and *ophthalmic benefits) under the national health insurance* scheme. These are of increasing importance, and their administration is not clearly known. This book is, and no doubt in future editions will continue to be, a trustworthy guide to the subjects with which it deals and for the public for which it is intended.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION.

THE Medical Women's International Association, of which Lady Barrett is president, will hold its quinquennial meeting in Paris from April 10th to 15th, and it is expected that representatives from some twenty countries will attend. In addition to the council and general meetings, at which the business of the association is transacted, there will be three scientific sessions on the afternoons of April 11th, 12th, and 13th, which will be open to all medical women, whether members of the association or not. The subjects for discussion are: (1) Sex instruction for children and adolescents (rapporteurs, Mme Montreuil Straus and Dr. Louisa Martindale); (2) Analgesia in midwifery (rapporteurs, Dr. Doris Kunkel and Mme Nechkovitch-Youtchetitch). The programme of social activities includes a reception given by the President of the French Senate at the Palais du Luxembourg and

another by the President of the Municipal Council at the Hôtel de Ville. Special arrangements have also been made to visit the Radium and Pasteur Institutes, as well as several of the most notable hospitals of Paris. The meetings will be held at the International Institute of Intellectual Co-operation (Palais Royal), by permission of the League of Nations. Further particulars may be obtained from the honorary secretary of the Medical Women's International Association, Miss Martindale, M.D., 28, Weymouth Street, London, W.1.

THE MANSON AND CHALMERS MEDALS.

THE Manson Medal, awarded triennially by the Royal Society of Tropical Medicine and Hygiene, is to be presented this year to Sir Ronald Ross. It was founded in memory of Sir Patrick Manson in 1922, and has been awarded to Sir David Bruce and Senator Ettore Marchiafava. Qualifications for the medal are contributions of outstanding merit to knowledge of tropical medicine and hygiene. The Chalmers Medal was founded in 1921 by Mrs. Chalmers in memory of her husband, Dr. Albert J. Chalmers. It is awarded every second year to the younger workers in the field of tropical medicine and hygiene, who must be under 45 years of age on June 1st of the year of award. It is to be presented this year to Major J. A. Sinton, V.C., I.M.S. Previous awards have been to Professor E. Roubaud, Professor Warrington Yorke, and Dr. H. Lyndhurst Duke. Though the Manson Medal was founded in memory of Sir Patrick Manson, its first president, the Royal Society of Tropical Medicine and Hygiene is endeavouring to establish a more substantial memorial in the shape of a permanent home for its activities bearing his name. To this end the Manson House Fund was started, and already subscriptions have brought in between £4,000 and £5,000, while £3,000 has been promised on loan without interest. It is hoped that a sufficient sum will be raised to enable the society to purchase suitable premises for its headquarters.

INFLUENZA.

IN the week ending March 23rd the epidemic of influenza was subsiding in most parts of the country. Notifications of pneumonia fell from 4,897 to 3,578, and deaths from influenza in the great towns of England and Wales from 1,552 to 966. We may reasonably expect that within a few weeks the rate of mortality will again be normal, and the severest recrudescence since the pandemic an unpleasant memory.

SIR WILLIAM PROUT, K.C.M.G., relinquished his appointment as consulting physician to the Colonial Office and the Crown Agents for the Colonies on March 31st. Dr. P. H. Manson-Bahr, D.S.O., has been appointed one of the consulting physicians in London to the Colonial Office and the Crown Agents for the Colonies from April 1st.

THE KING.

SINCE March 2nd two bulletins only have been issued, at intervals of a fortnight, and each has confirmed the general impression that the King is making satisfactory progress towards recovery. During the past month His Majesty has spent many hours in the open, enjoying the sunshine and sea air, and latterly has taken short walks about the grounds of Craigweil House. The bulletin of March 29th mentioned some rheumatism round the right shoulder, and reiterated the need for prolonged abstention from all except essential public duties, but was able to record progressive gains in weight, appetite, and sleep, and steady improvement in bodily and mental vigour.

CHEST SURGERY FROM THE MEDICAL STANDPOINT.

LUMLEIAN LECTURES BY DR. R. A. YOUNG.

THE Lumleian Lectures were delivered to the Royal College of Physicians of London on March 19th, 21st, and 26th by Dr. R. A. Young, C.B.E., senior physician, Middlesex Hospital, and physician, Brompton Consumption Hospital. Dr. Young's general subject was "A medical review of the surgery of the chest," and, remarking on the ancient foundation of these lectures—which dated back to 1581—he said that there was an explicit direction that they were to be on surgery; he felt, therefore, that his choice of a subject was in conformity with the wishes of the pious founders.

BORDERLINES BETWEEN MEDICINE AND SURGERY.

Border areas, said Dr. Young in his first lecture, were usually the scene of strife and conflict, and the zone of separation between medicine and surgery was no exception. Medicine was abstract in the main, dealing with deranged organs and disturbed functions, while surgery was essentially concrete and mechanical, concerned with removal, adjustment, and adaptation. Some of the greatest triumphs of surgery were in the failures of medicine, but, on the other hand, some of the greatest surgical tragedies occurred where surgery had been unwisely or unsuccessfully invoked in medical conditions. This was most emphatically true in surgery of the chest. If this branch of surgery was to advance there must be the closest co-operation between the physician and the surgeon. The surgeon could give the most dramatic assistance to the physician in disease of the lungs, bronchi, mediastinum, and pleura, in cases otherwise grave and even hopeless. What was needed was a better understanding on the part of the physician and the general practitioner of what surgery could do, and, perhaps even more, of what it could not yet achieve. In no branch of science was efficient and co-ordinated team-work more essential, but the physician should be the predominant partner or at least have the casting vote, the surgeon being his coadjutor or agent, not his substitute.

The question arose whether, in future, if specialization advanced to its logical development, diagnosis and treatment might not be concentrated in the hands of one person. The lecturer had an open mind on this subject, but he felt that at present the ideal arrangement was an understanding and critical co-operation between the physician and the surgeon, the team also including, for the successful surgery of chest diseases, the radiologist, the bacteriologist, the haematologist, the physiologist, the biochemist and the anaesthetist.

Briefly tracing the history of thoracic surgery, the lecturer said that the fundamental ideas in this branch of work and some of the earliest achievements stood to the credit of British surgeons, several of whose names, past and present, he mentioned. The reasons why surgery of the chest had developed later than other special applications of surgery included difficulty of access, fear of open pneumothorax, difficulty of collapsing cavities, risk of "mediastinal flutter," and fear of gas embolism. Modern developments in thoracic surgery had been rendered possible by a more accurate appreciation of the mechanics of respiration, improved methods of diagnosis, modifications in anaesthesia, rigorous selection and careful preparation of cases, and refinements in surgical technique.

Improved Methods of Diagnosis.

After some consideration of respiratory physics, the lecturer discussed the present improved methods of diagnosis, saying that diseased conditions within the chest offered some of the most difficult problems to the diagnostician. Fortunately, laboratory and instrumental methods yielded here perhaps even more assistance than in diseases of other systems. After a careful study of the clinical features of the case the first of the special methods to which resort would be made was x rays, the help of which it was difficult to exaggerate. Stereoscopic radiograms especially were sometimes of great value in establishing the depth of the morbid process and its relative

position to other structures. For mediastinal conditions oblique views might afford great assistance, while, especially in regard to abscess, bronchiectasis, and growth, a true or "dead" lateral view might give information of crucial diagnostic importance. The value of radiology in this field has been notably increased by the use of lipiodol, which enabled the bronchi to be mapped out to their finest ramifications. In his own experience he had found this measure of the greatest value in confirming and establishing the diagnosis of bronchiectasis, in determining whether this condition was localized or bilateral, and in distinguishing between it and abscess.

As for other special methods, bronchoscopy had established its value in intrathoracic conditions. Its employment in dealing with foreign bodies was now a commonplace. Thoracoscopy had enabled the conditions within the pleura to be seen clearly after a preliminary pneumothorax, also the situation and relations of new growths of the lung and mediastinum. Biochemical methods might serve an ancillary function, notably with regard to calcium content, blood sugar, blood urea, and other estimations. Complete fixation tests might give information with regard to syphilis, tuberculosis, or hydatid.

Surgery of the chest, the lecturer continued, should in nearly all cases be deliberate and unhurried. Emergency operations were exceptional; almost always there was time for the most meticulous examination, and for all necessary special investigations. The appeal to surgery should be made only after it was clear that medical measures were doomed to failure. On the other hand, in such cases the decision should be made as early as possible, certainly before the patient had become so debilitated that the risk of shock from operation outrode the chances of success. The mortality of these operations was steadily diminishing as surgical technique became more developed and the selection of cases more skilful.

Operative Technique.

The preparations of the patient varied somewhat in the practice of individual surgeons. Most surgeons insisted on rest in bed under careful observation for from seven to ten days before such an operation as thoracoplasty or lobectomy. If there was evidence of catarrhal process or any serious digestive upset, operation was postponed. In marked anaemia blood transfusion might be given, and before any operation in a condition of pulmonary excavation or dilated tubes, the utmost care should be taken to promote expectoration. The problem of anaesthesia in chest diseases was one of special difficulty. In patients with pulmonary tuberculosis it was advisable to employ local or regional anaesthesia when possible, and to use gas and oxygen rather than chloroform or ether for cases where general anaesthesia was essential. The technique of anaesthesia induced and maintained by an expert in the ingenious methods now available was admirable in its orderly and almost perfect adaptation to the needs of the surgeon.

The question of time was of great importance in a thoracic operation; therefore the ingenuity devoted to the production of special instruments for removing the periosteum from the ribs and for expediting other manipulations was very welcome, as were the time-saving details of operative technique developed by surgeons in their practice. After-care, especially in regard to the dressing applied and the degree of pressure exerted by it in cases of thoracoplasty, and the general nursing arrangements required by these patients, was of not less importance than the operation itself.

What was the help that surgery offered in the treatment of chest diseases? It helped by securing rest to the part involved, particularly in disease of one lung; by evacuating abnormal exudates at the right time and in the most effective manner; by removing foreign bodies; by causing the collapse of cavities; by excision or extirpation of growths; by the removal of diseased or damaged lung tissue which was beyond hope of repair; by decompression where intrathoracic pressure relations were disturbed; and by exploratory thoracotomy to discover whether radical surgical measures were practicable in an obscure condition. The lecturer briefly instanced the chief measures designed for these various ends, and spoke at greater length on pulmonary collapse, the basis of artificial pneumothorax treatment, pointing out that the beneficial effects of collapse forms of treatment comprised far more than the mechanical factors, and helped in bringing about the disappearance of the toxaemic features.

Surgery in Pulmonary Tuberculosis.

In his second lecture Dr. R. A. Young dealt with the treatment of severe pulmonary disease, in which, he said, the surgeon and the bronchoscopist seemed destined to take an increasing share. The earlier applications of surgery in pulmonary tuberculosis were directed chiefly to the drainage of cavities and removal of diseased areas of lung. Modern surgical methods were the outcome of the combined experience obtained by surgeons in the treatment of chronic empyema and by physicians in the use of artificial pneumothorax as a therapeutic measure. The decision as to the use of collapse treatment, whether medical or surgical, involved careful consideration of the type, extent, and localization of the disease, the clinical features of the case, and the age, personality, social state, and general condition of the patient, as well as his reaction to ordinary methods. Thorough *x*-ray examination, including the screen, was a very necessary preliminary.

Artificial pneumothorax was now so generally recognized as the routine treatment in certain cases that any detailed account of it was unnecessary. Thoracoplasty was its major equivalent, or, rather, substitute, since it should be remembered that the collapse induced by it was less than that obtained by a complete pneumothorax, though the results in successful cases were of the same type. The lecturer quoted an epigrammatic remark of Claus: "A good pneumothorax is better than thoracoplasty, but a good thoracoplasty is better than a bad pneumothorax." It should not be forgotten, however, that the collapse produced by this operation was permanent, whereas in most cases of pneumothorax treatment the lung could be allowed to re-expand at any time should extension of the disease on the opposite side or other emergency render this necessary. The safe rule was to consider for thoracoplasty all cases which were well suited for artificial pneumothorax but in which that treatment was impossible or had failed. In general, no patients should be submitted to thoracoplasty until the attempt at artificial pneumothorax had been made.

Indications for Collapse Treatment.

The type of case likely to benefit most from collapse treatment was that in which there was more or less extensive disease of slowly progressing type and chronic course in which the signs were clinically unilateral, and in which *x* rays showed very little damage to the opposite lung. For cases in this group thoracoplasty should only be considered if there was definite evidence of some natural tendency towards arrest, or, in other words, only if the processes of fibrosis and contraction predominated over those of caseation and softening. In haemorrhagic cases there were two indications for artificial pneumothorax treatment: (1) as a deliberate treatment in cases of repeated haemorrhage; (2) as an emergency measure in severe haemoptysis endangering life. Thoracoplasty in such cases should only be considered when artificial pneumothorax proved to be impracticable, and then only after a phrenic evulsion had been tried and had failed. Collapse methods were helpful in cases where partial arrest had been achieved by ordinary medical methods, but where the patient was left with cough and expectoration; also in cases with predominantly basic signs in which phrenic evulsion had failed to secure arrest. It was rather a paradox that cases in which spontaneous pneumothorax had occurred in the course of active disease of localized character did not do so well, when the pneumothorax was continued artificially, as ordinary cases of primary artificial pneumothorax.

Contraindications to this treatment might be afforded by either the character and extent of the disease or the general condition and temperament of the patient. When there was extensive active disease in the opposite lung, or laryngeal tuberculosis of the miliary type, or severe

renal tuberculosis, the treatment should not be pursued. In patients with poor physique a[illegible] with any considerable degree of [illegible], or with severe visceroptosis, or with chronic nephritis, again the treatment was contraindicated. In patients over the age of 60 the chances of success with artificial pneumothorax were comparatively small, while for thoracoplasty the age restrictions were more definite, few patients over 45 being suitable, though each case was to be judged on its merits.

The Operation of Thoracoplasty.

Paravertebral thoracoplasty was now established as the standard surgical method of inducing pulmonary collapse. The most important preliminary was to induce the patient to make every effort, immediately before operation, to clear the chest of expectoration. The general preference was for gas and oxygen anaesthesia. Some surgeons preferred the two-stage operation, for which the lecturer expressed his own preference. He had never known a patient decline the second stage, because, as a rule, the first brought sufficient improvement to encourage greater hopes from the completed operation. The amount of rib removed varied with the case. If the operation was carried out in two stages it was usual to resect parts of the lower ribs from the eleventh or tenth to the sixth or fifth at the first stage, and at the second stage to deal with the fifth or fourth to the first. The first rib was, as it were, the peg upon which the others hung.

Post-operative treatment was of as great importance as the operation itself. From numerous statistics it appeared that the immediate post-operative risk had now been reduced in expert hands from more than 10 per cent. to 5 per cent. or less. After the immediate post-operative risks were passed it was important to encourage the patient to re-educate and strengthen the muscles of the shoulder and arm. One remarkable feature about the operation was the comparative slightness of the deformity resulting.

It was usually said that artificial pneumothorax failed in 30 to 40 per cent. of the cases in which it was attempted. The commonest cause of failure was the presence of adhesions, and various attempts had been made to permit increased collapse in such cases. The lecturer briefly touched on these methods, including stretching and cutting.

Abscess and Gangrene of Lung.

Intrapulmonary suppuration resulted from such a variety of causes that it was not surprising to find its causation and treatment a subject of controversy. Abscess and gangrene were often associated, but in gangrene there was a larger degree of putrefactive necrosis and greater fetor, with a larger proportion of anaerobic organisms. A striking feature brought out by some American statistics was the frequency of pulmonary abscess after tonsillectomy, possibly due to aspiration of infective material under anaesthesia. In the acute stage of abscess formation, before the abscess was localized and had become encapsulated, surgical intervention was to be avoided. It was also undesirable, in suspected lung abscess, to use an exploratory needle, which might lead to rupture into the bronchus or pleura or to infection of the cellular tissues. Many successful cases of collapse of the lung induced by artificial pneumothorax were on record, but this was not suitable for deeply seated abscess. It was in subacute and chronic abscesses that some of the most striking results of surgery were to be seen. Surgeons could usually drain the cavity readily by a one-stage pneumotomy if the pleura was adherent at the spot over the abscess exposed by the preliminary thoracotomy. If no adhesions existed the two-stage operation was necessary. Pleural adhesions were induced by stitching the lung to the parietal pleura and inserting a gauze pack; five or six days later, if adequate adhesions had formed, the abscess could be opened and drained.

The lecturer briefly referred to tumours of the lung, drawing attention to the fact that there was one form of malignant growth of the lung in which lobectomy was practicable and had given encouraging results—namely, where the primary growth originated in the lung parenchyma at a distance from the hilum. He then turned to bronchial conditions and concluded with some remarks on bronchiectasis, for which, he said, many forms of surgical treatment had been suggested, and some already discarded. The general results could hardly be regarded as encouraging. The chief suggestions were to drain the cavity by pneumotomy as in abscess (clearly only suitable where there was a single large cavity); ligature of the branch of the pulmonary artery to the affected lobe (of little ultimate value); phrenic evulsion (worth a trial in obscure cases); thoracoplasty (less satisfactory in its results here, on the whole, than in tuberculosis); and lobectomy (not to be lightly recommended on account of its heavy mortality). It was to be hoped that in this condition surgery would be able to render fuller assistance at some time in the future.

ACUTE EMPYEMA.

In his third and concluding lecture Dr. Young dealt with surgery in pleural and mediastinal conditions, remarking that probably the pleura was one of the first parts of the body upon which surgery was successfully practised, while the mediastinum, owing to difficulty of access and complexity and importance of the structures contained, was one of the last to afford a safe field for the surgeon.

The first of the abnormal conditions in the pleura to demand consideration was acute empyema. The principles of modern treatment were clearly stated by Hippocrates, who advised no drainage until the fifteenth day, used irrigation, and recognized the necessity of keeping the wound open until the infection had subsided. Unfortunately, the Hippocratic rules were for many centuries disregarded or forgotten, and until recently the treatment of empyema formed a lamentable chapter in the history of medicine and surgery. One of the most notable advances was marked by the report of the Empyema Commission of the United States Army, consequent upon the experience of the great war. The Commission came to the conclusion, the high average mortality in the military camps notwithstanding, that death should not occur in cases of empyema, other than tuberculous empyema, unless complicated by such conditions as lung abscess and suppurative pericarditis. Graham, a member of the Commission, pointed out the marked difference between empyema due to the streptococcus and that due to the pneumococcus, and suggested that the high mortality in streptococcal cases was the result of applying in their treatment the principles commonly and correctly applied in pneumococcal cases. The most important outcome of the Commission's report was that empyema was not to be regarded as an acute surgical emergency requiring operation as soon as recognized. If there were acute symptoms these could usually be relieved by aspiration until it was clear that the time for operation had arrived, as judged by the examination of the pus and the general condition of the patient. Empyema was not to be regarded as an abscess, which should be opened as soon as recognized, but demanded the most careful investigation of cause, situation, and size. Too early evacuation was dangerous, and led to increased mortality; on the other hand, when frank pus was obtained, delay and inefficient drainage led to chronic empyema, "more easily prevented than cured." Dr. Young explained with great care the difference between streptococcal and pneumococcal cases. In the latter, as there was a walling off at a very early stage, earlier operation was permissible, and, indeed, desirable.

Methods of Treating Empyema.

The lecturer reviewed the procedures of aspiration and of drainage by closed and open methods. Continuous aspiration, often recommended, had its disadvantages; it was capable of giving good results, but it had not established itself for general use. When it had been decided to evacuate an empyema by thoracotomy there was still a choice of procedures. That an empyema could be successfully drained by a tube introduced through a simple intercostal incision was certain, but if the empyema was slow to clear up bone might form around the tube from periosteal irritation, and actually prevent the closure of the sinus after the tube had been withdrawn. The removal of a small piece from one rib ensured better drainage, and seemed rarely to lead to any bone infection. After the

pleura had been opened the routine method was to insert a tube and apply open drainage, with or without irrigation. This, if done at the right time and in the right situation, gave good results in most cases, but in general it was less satisfactory than the more modern method of closed drainage, with some special arrangement for securing negative pressure within the empyema cavity, and, if desired, with means to permit of irrigation. The simpler the apparatus the more likely it was to be effective. Two subsidiary aids to the treatment of empyema after thoracotomy consisted, one in efforts to assist expansion of the collapsed areas of the affected lung in order that it might fill up the pleural space caused by the empyema, the other (less generally accepted), irrigation of the empyema cavity, most generally by Dakin's fluid.

Chronic and Tuberculous Empyemas.

The causes of chronic empyema were too early opening in streptococcal cases, also unduly delayed opening, insufficient or ineffective drainage from incision at wrong spot, entrance of foreign bodies, such as swabs or pieces of drainage tube, formation of bony ring around drainage tube, pocketing, and broncho-pleural fistula. The first essential was *x*-ray examination, with and without lipiodol, to discover the size, character, and direction of the space or sinus and the presence of pocketing, or perhaps the existence of a second undrained empyema. The lecturer discussed various procedures, all of which, he said, however, involved operative manipulation in patients already debilitated by long discharges and diminished vital capacity, and so not to be undertaken lightly.

Pus developing in the pleural cavity in association with pulmonary and pleural tuberculosis was a most troublesome condition, and might be a serious complication. The term "tuberculous empyema" was somewhat loosely applied to a number of conditions, including tuberculous pyothorax, tuberculous pyopneumothorax, and cases of pyopneumothorax due to lung rupture or puncture in which secondary infection had occurred—a most grave condition. The outlook for all such patients, apart from active treatment, was extremely serious. The lecturer quoted some statistics furnished by his colleague Dr. L. S. T. Burrell in which a notably high mortality in cases in which purulent effusion occurred, as compared with those in which the effusion was serous, led Dr. Burrell to aspirate all cases in which there was pus, and to try to get the lung to expand. These purulent effusions in tuberculous disease should never be treated by open drainage, since this could only lead to pneumothorax with permanent external opening. Another method of treating cases with tuberculous effusion was by introducing oil into the pleural cavity; this method of oleothorax was still on trial, but seemed to be of use in selected cases.

Before leaving the subject of the pleura, the lecturer touched on haemothorax, the general principles of the treatment of which had been established by war experience. Operation was unnecessary in cases of uninfected haemothorax of small size. With large effusions, causing dyspnoea or distress, early aspiration was practicable and advisable. Early operation was indicated in large simple haemothorax in a state of massive clot.

Surgery in Mediastinal Conditions.

At present there was only a restricted field for surgery in the mediastinum. The real barrier was the danger of infection of the loose intervening areolar tissue. The superior and anterior mediastinum was exposed by splitting the sternum; the posterior by dividing and shingling the ribs upon one another after certain sections had been removed. Conditions in which the physician might require the surgeon's aid were suppurative mediastinitis, mediastinal tumours and cysts, and mediastinal emphysema. If suppurative mediastinitis had become localized it could be reached by the surgeon and drained. Chronic mediastinal abscesses were usually the result of tuberculous conditions of the mediastinal glands or of the bony walls of the cavity; they were usually to be treated like other "cold" abscesses, by aspirations and injections. Encapsulated tumours and cysts could, as a rule, be removed readily and without undue risk. A large majority of the primary growths in this situation were sarcomatous, and the chances of diagnosis of primary mediastinal malignant growth at a sufficiently early stage to warrant surgery were at present small. The relief afforded by decompression procedures was slight, and not commensurate with the severity of the operation. In rare cases of acute mediastinal emphysema, spreading to produce general subcutaneous emphysema, it might be helpful to make an incision near the jugular fossa and extract effused air by suction.

In conclusion, Dr. Young confessed his optimism with regard to the future of the branches of surgery of which he had been treating. An opened pleura properly safeguarded need now have no greater terrors than an opened peritoneum. Some measures, like paravertebral thoracoplasty, had already evolved to a high degree of scientific and practical adaptation. He hoped for further progress, including improved methods of pneumolysis, and in this hope he was encouraged by having seen phrenic paralysis develop from a relatively ineffective operation into one of wide application and usefulness.

Scotland.

Treatment of Cancer in Glasgow.

THE thirty-eighth annual meeting of the Glasgow Royal Cancer Hospital was held in Glasgow on March 22nd. The report for the past year stated that the ordinary income amounted to £7,668, and the ordinary expenditure to £9,527. Extraordinary income in the form of legacies, etc., had been received amounting to £7,143, with a credit balance of £5,284. Reference was made in the report to the recent gift of £10,000 by Lady Burrell for the purchase of radium. It had been decided by the directors to form a radium institute, and property adjoining the hospital had been purchased for that object. The institute was to be under the supervision of a full-time medical officer, and was to be available for the treatment of patients in Glasgow and the West of Scotland, while it was also hoped that radium could be lent to other hospitals in the neighbourhood. The chairman, Sir John M. MacLeod, stated that it had been decided to appoint a committee of lay representatives of the institutions concerned, which was to act in a purely advisory capacity without executive powers and with no control in the internal action of any of the hospitals. Mr. H. F. L. Fraser, in the course of an address, said it was now definitely established that radium offered hope for a very large percentage of cancer cases. In Britain they had fallen rather seriously behind in the question of radium surgery, for Britain as a whole had been too conservative in the adoption of new remedies. It was necessary that those who used radium should have special accommodation and special skill. The importance of radium had been realized by the Government, who had appointed a scientific research committee to investigate the situation. As a result of the report of this committee, an authoritative statement on the Government's attitude was to be made at an early date. It was to be desired that surgeons on the whole should be interested in the work of radium, so that knowledge of its application should not be left in the hands of one or two men. Co-operation among hospitals with regard to the purchase of radium and its application was also an urgent need, while some arrangement ought to be made whereby the radium in the West of Scotland would be available to all institutions, so that they would not require to buy more radium than was necessary to treat all their cases.

Royal Victoria Hospital Tuberculosis Trust.

The annual meeting of the Royal Victoria Hospital Tuberculosis Trust for the cure and prevention of tuberculosis throughout Scotland was held at Edinburgh on March 20th. The chairman, Sir Ralph Anstruther, said that they were gradually finding as the years went on that tuberculosis had been dealt with more and more satisfactorily. The death rate from all forms of tuberculosis in Scotland during 1887 was 265 per 100,000, while in 1927 it had fallen to 100. The past year was the fortieth anniversary of the foundation of the Victoria Dispensary

for Tuberculosis, and the beginning of the modern campaign against tuberculosis was marked by the establishment of that institution. At the present time tuberculosis dispensaries were to be found all the world over. Following the Victoria Dispensary, the Edinburgh scheme had included the establishment of a sanatorium (the Royal Victoria Hospital), a tuberculosis school, a working colony, a sanatorium colony at Southfield, a tubercle-free dairy, and a chair of tuberculosis in the University of Edinburgh. Three large institutions, constituting the chief factors in the tuberculosis equipment of the Edinburgh Corporation, were transferred by the committee of the Trust to the city of Edinburgh in 1914. Tuberculosis was little understood forty years ago, and one of the most striking advances had been the gradual shifting of the doctor's outlook from the adult or adolescent patient to the child. On account of the universality of infection in childhood, and the possibilities which such infection might involve for the individual and for the community, it was necessary that the advent of tuberculous infection should be watched for, and that appropriate measures should be taken to ensure that the infection became practically innocuous. A practical part had been taken by the committee in a movement which promised much for the Highlands and Islands of Scotland. An important educational mission throughout the whole of Great Britain had recently been undertaken by the National Association for the Prevention of Tuberculosis, and in connexion with this a senior medical officer and three deputy medical commissioners have been appointed to tour the country continuously. The deputy commissioner assigned to Scotland, Dr. Harley Williams, had already covered a large part of the country, and had held over 300 meetings of one kind or another. The research department was admirably equipped, and during the year several important lines of work had been undertaken. The committee desired to appoint two special workers in the research department, and would recommend the department to the consideration of benevolent donors, as it is anxious to obtain £600 per annum for this special purpose.

Work for the Blind in Edinburgh.

The Rev. Dr. Thomas Burns presided at a social meeting attended by the industrial workers of the Royal Blind Asylum, Edinburgh, held in Edinburgh on March 19th. He stated that this asylum was the second institution for the blind to be founded in Great Britain. The Blind Persons Act of 1920 had entrusted the care of these people to local authorities. The Corporation of Edinburgh had accordingly made arrangements with the Royal Blind Asylum by which they contributed an annual sum towards the maintenance of employable blind persons within their area, while the local and education authorities contributed towards the cost of training the workers. The cost of maintaining the ninety trainees at present in the institution was over £2,750 per annum. This Act of 1920, although it had benefited the institutional blind, had, however, done nothing to improve the condition of the aged and infirm blind, or those incapable of work. The question of obtaining after-employment for trainees was being carefully considered by the directors at the present time, and it appeared that new industries for the blind and new outlets for the work produced by them would be the best solution of the problem. The two new industries of cane chair making and quilt making, although satisfactory, were not sufficient by themselves, and still further new outlets must be found. This could best be done by co-operation between the workers and the management, since additional employment could doubtless be secured by putting into practice the ideas of the workers, and adopting them as staple industries of the institution if they proved successful. It was pointed out that in 1913–14 the wage paid to workers in the Royal Blind Asylum amounted to 20s. per week and under, whereas at the present time it was 50s. per week. A comparison was also of interest between the amount contributed to the general funds in 1909–10 and 1919–20, which amounted to £1,468 and £2,814 respectively, being an increase of 91 per cent., while in 1927–28 the increase over 1920 was £5,000, or 177 per cent. The voluntary contributions towards capital expenditure of the new workshops, etc., amounted to £10,576. The institution had never been in a more healthy condition during the long period of its existence, and the directors looked forward with confidence to the future.

Edinburgh Maternity Hospital.

The eighty-fourth annual meeting of the Edinburgh Royal Maternity and Simpson Memorial Hospital was held on March 22nd. The report stated that the total number of cases treated was 3,205, compared with 3,117 in the previous year. Progress had been made in regard to the proposed amalgamation with the Royal Infirmary; committees representing the Royal Infirmary and the hospital had been considering the maternity problem in Edinburgh, and the number of beds which the managers of the Royal Infirmary should be expected to provide in the new buildings, to be erected on the site of George Watson's School, in order to provide for the teaching of medical students and the training of nurses. It was decided that not less than 120 beds should be aimed at, and plans had been prepared which were being considered by a joint subcommittee. The accounts showed a deficit of £1,892, and this had to be withdrawn from reserve. The chairman said that the report emphasized the close connexion which existed between the town council and the Royal Maternity Hospital. Last year a fresh record had been set up in the history of the institution, for the figures represented 40 per cent. of the total births recorded in the city during the year. The ante-natal care of women was one of the great branches of preventive medical science, and the fact that 11,169 visits had been paid by patients during 1928 to the various clinics in connexion with the ante-natal annexe was a sure sign that it had the confidence of the public. He appealed for increased financial support to the hospital, and stated that it would be six or seven years before the amalgamation with the Royal Infirmary could be brought about.

Hospital for Cripples.

A meeting of the general committee and subscribers of the [illegible]tal for Crippled Children was held in t[illegible], Edinburgh, on March 20th. Lord Provost Sir Alexander Stevenson presided. The chairman said that a conference had been held two years ago at which it was clearly shown that an urgent need existed for the provision of a hospital for the treatment of cripples. They could now report that £50,000 had been raised, and this was a tribute both to the zeal of the committee and to the generosity of the people of Scotland. A site had been secured at Fairmilehead, which occupied a commanding position at the crest of a hill, and the building when erected would be one of the landmarks of the city. It was to be a central institution to meet the requirements of the south-eastern area of Scotland, and of the counties of Kinross and Clackmannan, and the western half of Fife. Although a sum of £75,000 was required, he had no doubt that the balance would be forthcoming. The constitution was unanimously adopted.

Perth Royal Infirmary.

The annual meeting of the County and City of Perth Royal Infirmary was held on March 4th. The report showed that the number of patients treated in the institution had been 2,666, while the expenditure during the past year had exceeded the income by £2,436. It was reported that the directors had decided to erect a nurses' home at an estimated cost of £15,000 on a site adjoining the hospital. Bailie Thomas Hunter, J.P., who proposed the adoption of the report, referred to the probability of closer co-operation between the hospital and the local authorities under the proposed new legislation, but expressed the hope of the directors that the institution would not in any way come under State control.

Glasgow Hospital Sunday Fund.

The thirty-fifth annual general meeting of the Glasgow Hospital Sunday Fund was held on March 20th in the Merchants' House, Glasgow. This fund was inaugurated in 1893, and the total sum disbursed since that time amounted to £229,467. As a result of the contributions for 1928 a sum of £9,600 had been divided among the three infirmaries in the city. Dr. James Macfarlane of the

Glasgow Royal Infirmary, presiding at the meeting, stated that the collections had been gradually declining since 1920, those of 1928 having fallen somewhat short of those of the previous year. Bishop Reid of Glasgow pointed out that though it was disappointing to find that the amount subscribed in the past year was down, they were thankful that the number of congregations contributing had increased from 522 to 555, while the number of Sunday schools had increased from 301 to 310.

England and Wales.

Voluntary and Municipal Hospitals under the Local Government Bill.

A MEMORANDUM[1] has been prepared by a special committee of King Edward's Hospital Fund for London, under the chairmanship of Mr. J. H. Whitley, dealing with the position of the voluntary hospitals after the Poor Law infirmaries have been transferred to the county authorities under the Local Government Act. The principle is enunciated that the maximum of efficient medical service cannot be achieved except by co-operation between the voluntary and the municipal hospitals. The committee, however, is of opinion that such co-operation will only be successful in bringing the municipal hospitals to a high standard if there is no interference, direct or indirect, with the voluntary element in the hospital service. Voluntary hospitals have acquired a tradition and prestige which, combined with the free scope they offer to initiative, have attracted to their service men and women of conspicuous ability. Success in creating an efficient and adequate hospital service will not be obtained by converting the voluntary hospitals into official institutions, but by developing municipal hospitals in co-operation with a vigorous voluntary hospital system. The committee suggests that supercession of the voluntary hospitals would represent not only a loss of about 64,000 beds and of contributions amounting to approximately nine million pounds annually, but of the great volume of voluntary work, lay and medical, which accompanies them. Continuous consultation between the authorities responsible respectively for the rate-supported and the voluntary hospitals is now provided for by the new clauses introduced into the Local Government Bill in the House of Lords. The committee proposes further that in each area there should be a standing joint hospitals conference, composed of equal numbers of representatives of the appropriate committee of the county or county borough council, and of the voluntary hospitals, and that this conference should consider which of the hospital needs of the area could best be supplied by the voluntary hospitals and which by the county hospitals. Wherever local circumstances permit, it is held that the appointment to the staffs of municipal hospitals of consultants experienced in voluntary hospital work would help to permeate the municipal hospital service with the spirit of the voluntary hospitals. The committee suggests that while it is impossible to lay down beforehand definite rules differentiating classes of patients and allocating them to different kinds of institutions, the difficulties might well be overcome in each locality by the proposed standing joint hospitals conference, in connexion with its periodical estimates of the hospital needs and hospital accommodation. In the training of nurses and of medical students there are already instances of interchange of facilities between the voluntary hospitals and public institutions; in the opinion of the committee it is highly desirable that there should be a further extension of these facilities, whereby the beds in the public institutions may be made generally available for medical education, both undergraduate and post-graduate.

The Birmingham General Hospital.

The arrangements for the first section of the Hospital Centre at Edgbaston, which is to be the extension of the General and Queen's Hospitals, Birmingham, are making progress, and the schedules for the proposed buildings will shortly be in the hands of the competing architects. As already mentioned in these columns, a site near the University has been offered by Messrs. Cadbury, and the suggestion is that this shall be shared by the two hospitals, which will eventually amalgamate. With this in view, both hospitals have abandoned the idea of extending their present buildings, except that the General Hospital is erecting a temporary ward in its grounds in order to meet the immediate call for more beds. In the annual report of the General Hospital, just received, it is stated that plans have been prepared for the erection of huts to accommodate sixty in-patients, and also for a new casualty department. Reference is made in the report to the loss which the hospital has sustained in the retirement of Professor Gamgee, who, as a mark of appreciation of his thirty-five years' invaluable service, has been elected consulting surgeon and presented with his portrait. The question of beds for paying patients has come forward prominently during the year. Usually there are about thirty patients in the hospital, admitted either on account of accident or for other good reason, who are able and willing to pay the entire cost of their treatment, as well as a fee to the doctor. In order to prevent the exploitation of the hospital and staff, the board is recommending the governors to set aside not more than thirty beds for such patients. Normally the charge is to be at the rate of four guineas per week, but in the case of patients who are able to pay a higher fee, who have been admitted on account of accident or emergency, or because the treatment they required could only be given at the general hospital, the charge is to be at the rate of six guineas per week. In the case of the four-guinea patients members of the medical staff are to be authorized to charge a fee not exceeding the amount payable to the hospital, and in no case greater than twenty guineas; in the case of the six-guinea patients the fee to be paid to the medical staff will be left to the discretion of the physician or surgeon concerned. The results of the Birmingham contributory scheme have exceeded expectations. It was at first considered advisable to lay down income limits to prevent exploitation by members of the scheme; but experience has proved this to be unnecessary, and by an arrangement with the Hospital Saturday Fund the certificates of works delegates are now accepted as proof of inability to pay for treatment privately.

Medical Education at the Royal Free Hospital.

A meeting was held at the London (Royal Free Hospital) School of Medicine for Women on March 21st to discuss the question of providing clinical teaching at the hospital for those who were affected by the recent decision of some medical schools to admit no more women students. Lady Barrett, who presided, said they were faced with the fact that they had to find room for the average number of women (about thirty) to whom these schools had been closed. The completion of the new building at the Royal Free Hospital for the obstetrical and gynaecological unit would set free forty beds, which would be available for general medical and surgical cases, and thus afford opportunities for teaching the extra students. But the hospital could not be asked to support those beds which could be used for private patients. It would be necessary that the beds should be endowed so that their cost to the hospital, about £5,000 a year, could be met. The beds ought to be ready in about three years, which would be the time when the new students would need their clinical instruction. It was very desirable that the medical and surgical facilities for teaching at the Royal Free Hospital should be equally extended with its other branches. If the proposal put forward were adopted there need be no women lacking facilities for a thorough medical education. Dr. Louisa Garrett Anderson said that a medical school for women alone had very great advantages over a co-educational school. Some of the French women doctors who visited the Allies' hospitals in France during the war had been surprised to find English women performing major operations, and had said that such facilities were not available in France, though they had had co-education for many years. Professor Winifred Cullis said she could not imagine the time when the London School of Medicine for Women would not be needed, even if the schools now closed to women were reopened to them. Preliminary measures were

[1] Relations between Voluntary Hospitals and Municipal Hospitals. Memorandum prepared by the Voluntary Hospitals (Local Government Bill) Committee of the King's Fund. March, 1929. George Barber and Son, Ltd., 23, Furnival Street, Holborn, E.C.4. Price 3d. net, 4d. post free.

adopted with a view to obtaining funds to increase the available medical and surgical beds at the Royal Free Hospital, so that no woman student should be debarred from entering the medical profession.

Centenary of King's College, London.

In connexion with the impending centenary celebrations of King's College, London, it is interesting to recall that almost from its inception it has played a large part in the development of medicine and surgery in this country. One of its first faculties was that of medicine; Herbert Mayo, an apostle of the Hunters, Richard Partridge, John Curnow, Bently Todd, who was largely responsible for the foundation of King's College Hospital, William Bowman, whose name is perpetuated in Bowman's capsule, Lionel Beale, and William Rutherford—the names of all these were written early in the pages of its history. Clerk Maxwell, Wheatstone, Daniell (of the Daniell cell), and John Millar Thomson were on the staff of the College when the time of the coming of Lister, and served as an inspiration to the faculty of medicine. Many of our present-day anatomists —Arthur Robinson, now of Edinburgh, Waterston of St. Andrews, J. E. S. Frazer of London, and Barclay-Smith —have been on the staff of the College; Alfred Garrod and W. E. Dixon worked on the pharmacological side. On the staff of the department of physiology have been Gerald Yeo, one of the founders of the Physiological Society, Halliburton, who was one of the first to recognize the importance of chemistry in the advance of medical science, Crookshank, subsequently the first professor of bacteriology in this country, Sir David Ferrier, remembered for his work on the localization of brain function, Sir Charles Martin, director of the Lister Institute, T. J. Brodie, whose clock, power table, and kymograph are in every physiological laboratory, Locke, who first succeeded in keeping the mammalian heart alive outside the body, Rosenheim, famous for his work on cholesterol, and Da Fano, whose work on histological neurology gave him an international reputation. The laboratories have been largely remodelled and extended, but the department of anatomy is still unsatisfactorily housed. In the appeal which has just been issued it is proposed, at a cost of £60,000, to build a new anatomy department in the immediate neighbourhood of the department of physiology.

Conference on Mental Welfare.

A conference on mental welfare will be held under the auspices of the Central Association for Mental Welfare in the Central Hall, Westminster, on April 25th and 26th. The subjects to be discussed are: (1) the effect of the Local Government Act, 1929, on the work of local authorities under the Mental Deficiency Acts; (2) the report of the special investigation carried out by Dr. E. O. Lewis on behalf of the joint committee of the Board of Education and the Board of Control on mental deficiency; (3) the report of the joint committee of the Boards of Education and of Control on mental deficiency, with special reference to educational and administrative problems concerning defective and retarded children; (4) experiments in the education and training of retarded children, with special reference to some of the recommendations of the joint committee. The sessions will continue from 10.30 to 12.30 in the morning and from 2.30 to 5.30 in the afternoon. Tickets, entitling holders to all the sessions, advance copies of the papers, and to the luncheon at the Hotel Metropole on April 26th, can be obtained at the offices of the Central Association for Mental Welfare, 24, Buckingham Palace Road, S.W.1, price £1 1s. Separate tickets for the conference and for the luncheon may be obtained at the cost of 10s. 6d. each.

An Alternative to Vaccination.

Dr. J. M. Ferguson, consulting medical officer to the Burnley Joint Hospital Board, in his report on the work at the Crown Point Small-pox Hospital during the year 1928, makes a number of interesting observations on the epidemic which broke out in the Burnley district in May, 1927. The disease at the onset, although it presented almost all the typical signs of variola major, followed a very different course. Only two of the patients had a temperature higher than 100° F., and in some, though not all of the cases, what little pyrexia there was subsided when the rash was fully developed. Secondary rise of temperature common in the major disease did not occur, pitting of the skin was absent, and there were no deaths. Of the 384 cases studied, 319 were unvaccinated, 65 had been vaccinated in infancy, in one the diagnosis was doubtful, and in another the vaccinal condition was not definitely established. The average age of the 65 patients vaccinated in infancy was over 50, and only two of them were under 21. On the other hand, of the 319 unvaccinated cases, 238 (131 males and 107 females) were under 21. Dr. Ferguson, while recognizing that small-pox is probably assuming a milder form, maintains that it is unwise to regard the danger of an outbreak of a severe epidemic as altogether passed. He makes the suggestion that in view of the poorly vaccinated condition of the town and district it might be well completely to ignore the isolation of minor cases and to allow the outbreak of the disease in its mild form to act as vaccination against variola major. Such a procedure, in his opinion, would not only be less costly than that at present adopted, but would help to render immune to small-pox persons who now decline to be vaccinated.

Ireland.

The Royal College of Surgeons in Ireland.

OWING to the illness of the President, Mr. T. E. Gordon, Mr. J. Atkinson Stoney, Vice-President, presided at the Charter Day dinner of the Royal College of Surgeons in Ireland, which was held recently in the College Hall, Dublin. Replying to the toast of "Prosperity to Ireland," the Governor-General, Mr. James McNeill, said that the Royal College of Surgeons began its corporate existence about a century and a half ago, when surgeons persuaded the Government of that time that surgery and hairdressing could not be efficiently combined. Their predecessors had foresight. Each art required now more knowledge and skill than any one person could be expected to possess. In India, however, he found about thirty-five years ago that the arts were still united, though the combination was dying out. In his time surgery in Western India was made known to the people largely by his countrymen. His first but not his only district surgeon was an Irishman whose skill won respect, and whose personality inspired universal affection. Most of the surgeon-generals in his presidency in his time were Irish surgeons, and when he was sent on duty to the West Indies the first surgeon-general he met was an Irishman. When he took a flat in London some years ago he found a good Irish doctor near him, and when he moved into a house he found in the same street an Irish doctor, who made illness a very pleasurable, though transient, diversion. As regards the general condition of the Service, he thought it was very much like the state of the surgical profession: it was doing wonderfully well in spite of some unfavourable circumstances. It was not only anxious to do better, but it was energetically improving from year to year. A friendly surgeon had recently said that the correct analogy in this respect was not with surgeons but with their patients, the great majority of whom were cheerfully ready to endure anything in the hope of getting well. The small minority were divided into two classes: one class wanted to be made so well by surgery in one day that they could compete in the Tailteann games on the next, while the other class wanted to know why they should be bothered to accept anything so inconvenient as surgery, however ill they had made themselves. The Governor added that his prime object in coming to the Charter Day dinner was to acknowledge what the College had done for Irish surgery, and to express his sincere sympathy with, and respect for, Irish surgeons, who were maintaining the traditions of an honourable profession. Sir William Taylor, proposing the toast of "The Sister College," said that there had been very close association between the College of Surgeons and the College of Physicians for nearly fifty years; both had done a great deal for the profession. Not only had they trained men to practise

their profession throughout the length and breadth of Ireland, but at least 75 per cent. of them were qualified to practise in the various territories of the British Empire. Dr. Winter, President of the Royal College of Physicians of Ireland, responding, said that both Colleges were proud of their traditions and the men that went before them—men who added credit to themselves and lustre to the Irish medical school. He hoped that the Government would in the near future see its way to endow medical research. The toast "Our Guests," was proposed by Sir William De Courcy Wheeler, who coupled with it the names of Mr. William Carrigan, K.C., Mr. E. H. Burne, President of the Incorporated Law Society, and Mr. David Barry, O.B.E.

India.

The Opium Habit.

LIEUT.-COLONEL R. N. CHOPRA, I.M.S., who is professor of pharmacology at Calcutta, has recently contributed a very interesting article on the present position of the opium habit in India.[1] It will be remembered that the Royal Commission on the use of opium in India that reported in 1895 extenuated the use of the drug in that country. Opium was represented as a treasured household remedy used extensively for medicinal, semi-medicinal, and veterinary purposes. Moreover, even opium addiction was represented as being comparatively harmless to Indians, for it was stated that moderate indulgence led to no injurious effects and did not shorten life; but that, on the contrary, it tended to ward off sickness and lessened the discomfort consequent on poor food and gastro-intestinal and malarial disease. Professor Chopra has made an exhaustive study of the consumption of opium in the various regions of India, and also of the cases of 875 opium addicts. His conclusions disagree totally with the comforting conclusions of the Royal Commission. The following are some of his conclusions:

"Our inquiries show that the habit, once formed, cannot be easily abandoned. Nor is it true that Indian addicts generally do not increase the dose and keep to small quantities without ill effects. . . . We failed to find any facts which could substantiate the statement that Indians had a greater degree of tolerance to opium and were less susceptible to its ill effects. . . . The habit once formed is as difficult to break among Indians as among any other people. . . . It [the habit] undoubtedly leads to physical, mental, and moral deterioration, and we have ample proof of it in the series of cases we have studied."

The general conclusion appears to be that the opium habit produces the same effects in Indians as it does in Europeans, and that its non-medical use is as undesirable in the one case as in the other. Professor Chopra proves by his analyses that opium addiction is a strictly localized habit in India. In most districts in India the consumption of opium is less than 4.5 kilos per 10,000 of population, which is the figure given by the Advisory Committee of the League of Nations as the opium requirement for medicinal purposes. On the other hand, a minority of districts show an enormous consumption—for example, six districts in Assam show an average consumption of twenty-five times their medicinal requirements. These figures seem clearly to indicate that there is no universal demand or need amongst the inhabitants of India for opium for non-medicinal purposes, but that opium-eating is a habit confined to certain localities. It is satisfactory to know that the Indian Government is taking steps to try to reduce the opium consumption in those areas where the consumption of opium is more than five times the amount needed for medicinal purposes.

Small-pox in Bihar and Orissa.

In the most recently issued public health report for the province of Bihar and Orissa, Lieut.-Colonel J. A. S. Phillips, the officiating director of public health, refers to the difficulties experienced in securing the vaccination of children as a measure of protection against small-pox, and mentions that among certain classes opposition to vaccination is influenced by religious beliefs. The death rate from small-pox in 1926 and 1927 was 1 per 1,000; this disease occurs in all districts every year, assuming epidemic dimensions at intervals of six or seven years. The period of these cycles suggests that the immunity conferred by primary vaccination is practically exhausted in this term, and since only a small proportion of newly born children are protected each year the number of susceptible children at the end of each cycle is very great. Efforts have been made by officers of the health department, in inspecting vaccination work, to ascertain the proportion of newly born children protected. In one area it is stated that, after allowing for infant deaths, only one-tenth of the remainder are vaccinated annually. A severe and prolonged outbreak of small-pox occurred in 1926 and 1927, accounting in each year for about 34,500 deaths, the death rates in certain districts in 1927 approaching 2 per 1,000 from this disease, while in one town the rate was 5.9 per 1,000. The question of making primary vaccination compulsory throughout the province is now receiving consideration, and while there are apparent financial difficulties Colonel Phillips points out that any additional expenditure involved would be easily justified. As already mentioned the religious beliefs of certain sections of the population constitute another obstacle to progress in this direction. The classes concerned hold that small-pox is a visitation of the goddess Sitala and that it is inexpedient to interfere with her workings.

[1] *Indian Journal of Medical Research*, vol. xvi, No. 2, p. 339.

Child Welfare in Burma.

The medical inspection of schools and school children has been steadily improving in Burma during recent years, but Lieut.-Colonel E. Bisset, director of public health for Burma, states in his report for 1927 that, until a fully organized public health staff is created in each town and district, it will be impossible to give adequate attention to the 350,000 children attending the 5,600 vernacular schools. In the meantime, only the children of the comparatively well-to-do are being cared for systematically for the most part, and these probably require it less than the children of the poorer classes. Medical inspection is compulsory in all Government schools other than vernacular schools, but it is still optional in aided establishments. Complaints have been received from a large number of school medical officers that many parents seem quite apathetic as regards the health of their children, and that advice given is not followed. Thus, at one school, out of 139 cases of defective teeth, only 12 were cured. A measure of improvement has followed the extension of invitations to parents to be present during the inspection of their children, and some medical officers have reported a considerable quickening of interest where this practice has been adopted. At one school the employment of a trained nurse to ensure obedience to the instructions given by the medical officer has proved very effective. Elementary hygiene is now being taught in the schools, and it is hoped that this will result eventually in the appearance of a new generation of parents more intelligent and responsive than their predecessors. Various hygienic improvements have been effected in several schools, but a regrettable feature noticed in many cases was the apparent absence of any facilities for recreation. Colonel Bisset adds that, in view of the importance of organized games and drill in physical, mental, and moral training, it is to be hoped that improvement will follow in this respect also.

Leprosy Survey in Travancore.

With a view to inaugurating a campaign against leprosy in Travancore a health survey party, under the auspices of the Indian Council of the British Empire Leprosy Relief Association, has commenced an investigation in Trivandrum. It is hoped to determine the actual incidence of leprosy in Travancore, where it is believed to have increased by 85 per cent. in the last ten years. Which classes of the population are the most affected will be determined, and a comparative study is being made of the conditions in the leprosy and non-leprosy areas. It is hoped that information of etiological and prophylactic importance will thus be obtained. The introduction of new methods of treatment in the State Leper Asylum and open leprosy clinics will be undertaken. The Travancore Government is assisting the survey party actively, and has given facilities to subordinate officers of the medical department to undergo special training, which will enable them to co-operate more actively in the coming campaign.

Correspondence.

THERAPEUTIC VALUE OF ULTRA-VIOLET LIGHT.

SIR,—In the Medical Research Council's report reference is made to two investigations of the effects of rays from the mercury vapour lamp upon the health of a group of "subnormal" infants and a group of school children in London. The scientific value of these investigations is rightly assessed highly because in both cases "control" groups were studied; when, however, the Council fails to admit as evidence all the other clinical work that has been done on the subject, many clinicians whose experience of ultra-violet light in rickets has made them enthusiastic in favour of it will feel bound to protest. Ascertained scientific facts may be the truth, but that they are not necessarily the whole truth is a matter of medical history.

The Council states that "prolonged researches . . . give no scientific reason at all to suppose that the treatment of rickets is better effected by ultra-violet rays falling on the skin than by direct provision of the necessary food values." But those of us who have worked at light clinics in industrial districts, and who know so well the practical working conditions, will be profoundly unconvinced. We remember the wretched specimens of infants with digestion impaired, unable to tolerate cod-liver oil, and the ignorant, careless, or harassed mothers who could not be depended upon to give it. We remember how often cod-liver oil failed us under those conditions, and how, on the other hand, ultra-violet light effected not only a rapid cure of rickets, but a marked improvement in the general health. I, personally, tried dietetic and hygienic measures in the treatment of hundreds of cases of rickets at Motherwell child welfare centres from 1919 to 1924, and I freely confess that the adverse conditions proved too much for me. From 1924 to 1925 a series of cases which had practically failed under this treatment responded rapidly to ultra-violet light. In 1925 and 1926, when the light clinic was organized, I treated 121 cases, and rapidly achieved satisfactory cure in 95 per cent., as well as astonishing improvement in general health in the vast majority. Of course, I know that all this is not "scientific," but the success achieved was sufficiently remarkable to satisfy all concerned. In Dr. Katherine Gamgee's book on *Artificial Light Treatment of Children*, case histories in rickets are given, showing precisely similar results to mine. The Medical Research Council states that reports submitted from artificial light centres "exhibit much variation of opinion," but if these reports are studied with discrimination, I believe that no appreciable difference of opinion will be found as regards (1) the rapid cure, even under adverse conditions, of the bony lesions in active rickets, and (2) the remarkable improvement obtained in general health in such cases, including improvement in muscle tone and associated activity in waking hours, the disappearance of apathy, fretfulness, and sleeplessness, and the appearance of happiness and well-being.

The reports on the London children quoted by the Council deal with a different class of case altogether, but there is no clear indication of this distinction in the Council's statement. On the basis of these two limited investigations and of current laboratory findings, the Council seems prepared to condemn artificial light centres for rickets as unnecessary and about fifty times more expensive than alternative methods of treatment. In its estimate of cost, it appears to have entirely overlooked the fact that many children can be treated together round the lamps, thereby making the cost per case very low. Huldschinsky stated that "a single quartz lamp rationally employed can cure annually some 1,000 rickety children." But much more serious than any question of cost is the fact that the Council ignores the almost unanimous body of opinion in favour of light treatment of *active rickets*, expressed by clinic workers who have personal experience of it, at any rate, in the industrial districts of the North. It is a gesture which, if successful, would deprive such workers of a therapeutic armament which, in their hands, has been productive of immense benefit to child life, and such a thing at this late stage is unthinkable.—I am, etc.,

Leicester, March 23rd. H. STANLEY BANKS.

COLLES'S FRACTURE.

SIR,—It is to be hoped that the discussion in your columns on the above subject will lead to an improvement in the treatment of this common fracture. I cannot agree, however, with Mr. Bankart in his condemnation of the method of reduction taught us by Sir Robert Jones; personally, I prefer it to the brute force advocated by Mr. Bankart. Preliminary disimpaction is, in my opinion, a most useful manœuvre, which obviates the necessity for great force in recent cases. When the fracture is not seen till two to four weeks have elapsed since the receipt of the injury, reduction is, I admit, impossible without the use of all the force of which the surgeon is capable; a wedge or other support is then a useful aid to the surgeon's hands.

Anatomical perfection is undoubtedly desirable, and should be our aim in all fractures, but every surgeon knows that in many cases small imperfections in the reduction make not the slightest difference to the functional result. The chief difficulty that besets the inexperienced practitioner is to know what minor displacement is of importance, and what he may safely disregard. In Colles's fracture, for instance, slight backward displacement is of no moment, provided there is no backward tilt of the lower fragment. It is entirely unnecessary under such conditions to inflict a second anæsthetic and manipulation on a patient in order to try to achieve anatomical perfection, as advised by Mr. Watson Jones. In the presence of much comminution it may be even unwise to be too ambitious. The older the patient the greater the latitude permissible in this respect. If the fracture had occurred higher up in the shaft, no surgeon would worry about partial backward displacement of the lower fragment provided the fragments lay in parallel planes. When, in a fracture of the Colles's type, the articular facet for the ulna is broken, every effort should be made to obtain absolutely accurate replacement.

In the final paragraph of his remarks Mr. Bankart rather implies that surgeons in charge of fracture clinics deprive house-surgeons and others of their opportunities of setting fractures. I cannot believe this is so. Whether a hospital possesses a fracture clinic or not the fractures must be treated, in the first instance at any rate, by the casualty officers and their assistants. Only after the fracture has been set and a second radiogram taken should the case be seen in the fracture clinic. This clinic should be attended by the casualty officers alternately. If further manipulation is necessary this should be done, if possible, by the officer responsible for the first setting, and only occasionally by the surgeon in charge. The functions of this surgeon, it seems to me, are to supervise generally the treatment of fractures in the hospital; to criticize, advise, and encourage those who have the advantage of seeing the cases shortly after the receipt of the injury—the ideal time for reduction—and whose duty it is to set the fractures; to undertake manipulation or operation only in selected cases; to teach the students attending the clinic; and lastly, to act as controlling liaison officer between the casualty and the massage departments. These are the lines on which we have run the fracture clinic at King's College Hospital, and they are, I submit, the right lines if our chief object is to be achieved—namely, to maintain at as high a standard as possible the routine treatment of the fractures seen in the casualty department of the hospital.—I am, etc.,

London, W.1, March 26th. H. A. T. FAIRBANK.

SIR,—I have read with much interest Mr. Bankart's able article and Sir Robert Jones's criticism of it. Sir Robert says, "the principle which underlies my very simple procedure is extension of the radius, pronation of the lower fragment, and supination of the upper." The patient comes under observation with the fracture firmly impacted, and until this is freed I fail to see how the above can be effected.

The whole matter centres around the question of impaction. Except in the hands of Sir Robert Jones and those who have attained his skill, extension of the radius merely means extension of the wrist-joint, and completely fails in the majority of cases to disimpact the

fracture; if successful, then the pronation of the lower fragment and supination of the upper can be carried out. I have on many occasions endeavoured to follow Sir Robert's instructions, with uniform want of success, hence I agree with Mr. Bankart that to attain disimpaction and subsequent reduction force and leverage are necessary; nor have I seen any injury to nerves or other soft structures.—I am, etc.,

Cooden, March 29th. DOUGLAS DREW.

DIAGNOSIS OF EARLY PREGNANCY.

SIR,—The response to the letter of Professor Johnstone concerning the Zondek-Aschheim test for pregnancy which appeared in your columns on February 9th (p. 264) has been most encouraging. Already some ninety tests have been made, and in such cases in which further clinical reports have been received the diagnosis as established by the test has been confirmed.

Experience has shown, however, that the working of the pregnancy diagnosis station could be made easier and more fruitful if certain matters of detail were improved. Commonly too much, too little, or too stale urine is sent, and often in packages that are too easily broken in transit. The requirements are 2 oz. of fresh morning urine in a chemically clean bottle, enclosed in a package that will withstand the dangers of the journey, and accompanied by the following information: date of last menstrual period; parity; menstrual history; history of any severe medical disturbances.

It would also appear necessary to emphasize the fact that the test cannot be made free of expense; mice have to be bought and kept, and it is to cover the cost of these that a charge of 5s. for private cases and 1s. 6d. for institutional cases is necessary. A postal order should therefore be enclosed in the package.—I am, etc.,

Pregnancy Diagnosis Station, The University, Edinburgh, March 23rd. F. A. E. CREW.

OBSTETRICS IN GENERAL PRACTICE.

SIR,—We general practitioners who read the frequent letters and articles in the *British Medical Journal* on the present state of obstetrics in England, and the maternal mortality rate, must feel ourselves in the position of a "buffer state" which has to take the blows of opposing forces, and still remain standing.

In the one camp the consulting obstetricians demand a maternity service restricted to their ranks, delegating the physiological act of childbirth to the status of a major operation for a pathological condition; on the other side are the public health authorities, who sometimes admit the value of the family doctor as a regular standby, but consider that the ideal would be for the specialist to see every patient in the course of pregnancy and in the early stage of labour.

While the contest wages over his patient head the general practitioner still carries on his maternity work, endeavouring to forestall avoidable dangers scientifically, and, in emergencies, often performing feats of skill single-handed.

Does it ever occur to the obstetric specialists that they only see the beginning and end of a maternity case, and that, usually, only under hospital or nursing home conditions? How cognisant are they of the terrible slum dwellings in which so many decent women have to bear and rear children, and the doctor fights a losing battle to deliver them under aseptic conditions? Have they any idea of the difficulties of conducting a labour in a single room of a slum tenement, where, maybe, both roof and floor are giving way, the one window is hermetically sealed, and the gas fittings are coming away from the wall? Or of working in a one-roomed dwelling where the sewer gas sends its foul emanations into the room, which fact has been reported without success to the landlord and public health authority?

Surely a little thought and study of actual conditions would show that the fault of the continued high mortality rate lies not with the doctors and midwives, but with the housing conditions in which they carry on their faithful work. Would it not be better if, instead of so lightly casting aspersions on the general practitioners of this country, the obstetric consultants and public health authorities united with their other medical colleagues to insist on better housing and the provision of more municipal maternity homes?—I am, etc.,

Oldham, March 23rd. MARY G. CARDWELL, M.D.

THE ART OF SURGERY.

SIR,—In his very kindly review of my book (March 30th, p. 603) your reviewer objects to my description of surgery as an art, on the grounds that the surgeon creates no new moral or spiritual experience, and that the values he learns to perceive are only material values. Now a short time ago I spent a happy hour contemplating the glories of the Venus of Milo in the Louvre, and yet the closest examination failed to reveal any evidence of any moral or spiritual element in its structure, and it appeared to be formed of the most substantial material. It is true that I am not a psycho-analyst, and I was probably blind to the suggestive symbolism underlying its apparently innocent outward form. But what I did perceive was that here some great artist, whose name we shall never know, had seen beneath the surface of what was perhaps some very ordinary human form, and with matchless skill of hand and eye had impressed on a mere block of marble the flowing grace, the lovely poise, the calm yet half-expectant gaze which have made his vision immortal.

It is precisely for this attitude of the artist that I make my plea. I ask my students to realize that diagnosis does not consist in the collection of laboratory reports, but in trying to see beneath the surface both of the patient and of his story; and when I go round the wards I try to impress upon them that somewhere beneath the surface, even in the most ordinary case, there may lie hidden undreamt-of possibilities. It would undoubtedly be of great advantage to all of us if many of the artists of the present day would give up the use of materials altogether and would confine themselves to moral and spiritual experiences; but I trust that future generations of surgeons will realize the essentially artistic nature of their work, and will pursue their calling as one of the greatest of the arts.—I am, etc.,

London, W.1, March 30th. H. S. SOUTTAR.

TONSIL PUNCTURE.

SIR,—We were much interested in the paper by Dr. Ramsay and Mr. Pearce on tonsil puncture published on March 23rd (p. 543). As the authors made a reference to a former publication by one of us, E. Cronin Lowe, and being interested in any advance resulting in a better method of obtaining suitable material for bacteriological examination from likely foci, we feel that this short note may add further thought for your readers.

The method of obtaining suitable organisms by means of tonsil puncture is indeed interesting. It strikes us, however, that the needle in all probability penetrates or may lodge in tonsillar crypts in its course, and therefore the organisms obtained by this method are those found actually in the tonsillar crypts and not necessarily in the tissues surrounding the crypts. We have performed such examinations upon tonsils as a definite routine of general investigation in all cases similar to those mentioned by the authors, our technique being identical in the preparation of the patient, but a straight, right-angled firm platinum wire was used to explore the tonsils for crypts, large and small. On many occasions clinically "normal" tonsils and their fibrotic remains contain crypts, single or multiple, into which such a platinum wire may be pushed, sometimes to a depth of half an inch. From such specimens it has been our invariable practice to emulsify the collected material in approximately two drops of saline solution in a tube with a wide mouth immediately after collection. From such an emulsion approximately one-half is taken from this tube and isolated by the successive streak method upon a blood agar plate. This, after a suitable period of incubation, provides a concise idea of the total organisms present, and the approximate incidence of each. It will probably be agreed that blood agar is a most suitable medium for the organisms which are likely to be present from such a focus to grow upon.

To the remaining emulsion in the wide-mouth tube 5 c.cm. of the patient's blood is added and incubated immediately. On the following day subcultures are made upon blood agar plates, and the further incubation and examination of the resulting cultures, if any, are carried out.

There appears to us to be little doubt that such technique as referred to above is preferable to that laid down by Ramsay and Pearce, since it not infrequently happens that by the "pathogen-selective method" the growth of a presumably pathogenic organism is enhanced, or appears when it is not obtained by the ordinary control method of culture. Again, employment of the direct method of cultivation gives a fair idea of the number of organisms inoculated with the whole blood, and is therefore an index of overplanting or not, which may quite easily be done. Furthermore, the simple method of tonsil crypt culture, as described above, has, in a group of 100 rheumatic cases examined by us recently, shown very similar findings to those of Ramsay and Pearce, in that 20 per cent. were negative pathogen-selective cultures, and 80 per cent. positive by the same method. This, therefore, suggests that there is no evidence of better cultural results obtained from the tonsil puncture method, interesting though it is, than from those obtained by using the simple crypt culture technique.

We have little doubt that this pathogen-selective method, originated by Solis-Cohen, is a definite advance in an attempt to obtain the pathogenic organism or organisms from suspected foci. Theoretically, the method "holds water," and many points could be put forward as to its feasibility, but the time is inopportune. The application of such a method, although encouraging, needs a great deal more study before final conclusions are stated, and since many hundreds of cases falling into definite clinical groups have been examined by such a method by us, we welcome this publication.

Let us not, however, again fall into disrepute on the value of tonsil cultures, as we did over the wholesale extraction of teeth, but rather view the tonsil as one potential area for organisms or their toxins to be absorbed, and at the same time test out fully by similar methods all other potential foci of infection.

We fully agree that the pathogen-selective method is of great importance to our colleagues, for it frequently shows where the focus of infection lies, and therefore calls for conservative or radical treatment. There is little doubt that the time has come for a closer co-operation between the clinical pathologist and his colleagues; and so long as we remember there is truth in both methods of attack, then marked curative therapeutic advance will be made. We hope that many more pathologists will be stimulated to apply this fascinating method of pathogen-selection, but a further warning note should be observed—namely, do not stray too far from the original application of the method—for what appears at the present time to be a valuable and simple technique may, as the result of modifications, become valueless.—We are, etc.,

E. CRONIN LOWE.
HUGH SMITH.

Liverpool, March 27th.

DEEP X RAYS AND THE CELLS OF THE BLOOD.

SIR,—The article in the *British Medical Journal* of March 23rd (p. 542) by Drs. Knott and Watt on "Some effects of deep *x* rays upon the cells of the blood" raises an important point as to the reaction of certain localized infections to radiation treatment.

In their experiments with normal and leukaemic blood *in vitro* they found that irradiation produced complete loss of all phagocytic power in the polymorphs within about thirty-five minutes. If the same blood changes occur *in vivo* it will be necessary to reconsider the question as to why a single dose of *x* rays so often produces a favourable result in cases of boils, carbuncles, and in the early stages of erysipelas.

Recently I was able to abort a boil on the upper lip of a young boy. Lymphangitis, enlarged submaxillary glands, and a high temperature were present, and it appeared as though incision would be inevitable. However, after an application of *x* rays, resolution rapidly followed, and the temperature dropped to normal.

On other occasions I have observed that carbuncles which have resisted ordinary treatment have responded quickly to *x*-ray therapy. Good results have also been reported by Coyle, Ross, Dunham, Richards, Lewis, and Hodges; the last of these published a full account of his results in the *Journal of the American Medical Association*, October 24th, 1925. In this report he states that in moderate-sized carbuncles of the forearm, with lymphangitis extending nearly to the axilla, the pain was relieved and the red lines of lymphangitis had disappeared within eighteen to twenty-four hours following *x*-ray treatment. He found irradiation particularly valuable in large carbuncles which commenced to discharge copiously within twenty-four hours, this being followed by local and general improvement. Hodges suggests that these good results are due to the *x* rays causing a greater activity of the cells and an increase in the phagocytic powers of the blood. The response to the treatment is so rapid that it is probably not due to any action on connective tissue cells.

We have therefore to face two facts. Laboratory experiments *in vitro* prove that the phagocytic powers of the blood are abolished by irradiation, while clinical observations on the living subject suggest (but do not prove) that phagocytic powers are increased. This apparent contradiction should open new fields for research.

First, do localized infections respond well to irradiation because of an increased phagocytic index? Secondly, if the phagocytic index is not increased, what is the mechanism which is responsible for the rapid improvement? Thirdly, will the experiments *in vitro* show the same result with medium voltage therapy as with deep *x* rays, since it is the former which are used with such good results in the treatment of skin infections?

Drs. Knott and Watt suggest that the destructive effect on the blood is due to secondary radiations. With medium voltage *x* rays the proportion of secondary radiations will be much less, and it is possible that the smaller dose may produce a stimulating and not a depressing effect on the phagocytic power of the leukocytes.—I am, etc.,

PAUL CAVE.

London, W.1, March 25th.

THE CIRCULATION UNDER THE SPHYGMOMANOMETER CUFF.

SIR,—In respect of Sir James Barr's second letter (*British Medical Journal*, March 9th, p. 475), I do not think that any further comments are called for from me; it remains that I can only regret that he did not give his consideration to my *argument* and give me the benefit of his criticism. Professor Leonard Hill's letter, on the other hand, has interested me a great deal. It is, however, very difficult in a description, to follow all the details of a complicated apparatus, and I feel that only careful study of the apparatus *in situ* and *in actu* can suffice to do justice to the experiment and the experimenter. I am not clear whether, in all the observations on the frog's web, the web itself is under direct pressure or not. If *not*, then in these the phenomena observed would correspond rather to those witnessed in the segment of the arm distal to the cuff, whereas my main argument regards that which happens in the cuff segment; this is precisely where the importance of direct inspection comes in.

Accepting, on Professor Hill's authority, the essential correspondence of the working of his apparatus with that of the sphygmomanometer, I note that he describes minute the effects of a rising pressure applied to the frog's leg and observed in the web of the foot; it is to these observations that I wish to draw particular attention, as they seem to me to bear out certain conclusions which I have come to, and which are vital to my argument. Let me first state these conclusions as briefly as possible.

1. The primary effect of loading the surface of the cuff segment must be to empty completely, and more or less extensively, the veins of this segment, and so to cut off the escape of a certain bulk of blood via the veins. The absence of any impediment, towards the heart, exacts this conclusion.

2. The subsequent effects of the continued rise of the cuff pressure may be divided into two stages. Stage I, which ends at the point when the cuff pressure becomes equal to the pressure in the brachial artery. When this happens there is complete stasis throughout the trunk and branchings of the brachial artery in the cuff segment. It is to be noted that, the opposing forces being in exact equilibrium, the channels and orifices of the artery are still fully patent, there being no surplus of force to compress them. Stage II, which, beginning with stasis and open channels, ends with the disappearance of the pulse at the wrist. The whole duration of this stage is occupied by a summation of increments of pressure *in excess* of the intra-arterial pressure, which remains a constant. The first, smallest rise destroys the equilibrium present at the end of Stage I, and thence onwards the volume of blood under consideration is in the grip of a rising unopposed pressure, and it begins to move along the line of least resistance—that is, towards the open mouth of the brachial artery at the upper edge of the cuff. The blood, being as it were encompassed by the extravascular surplus pressure, must move *en masse*, and with each rise, however imperceptible in its beginnings this movement may be, there will be some escape of blood from the orifice of the brachial artery and a corresponding emptying of the outlying capillaries and arterioles at the periphery of the blood mass. In the course of time such a process continued would express the whole of the imprisoned blood, for the grip is trying all the time to obliterate the arterial channels, but this cannot take place until the whole of the blood is expelled. It is to be noted particularly that this expression is by a *reversed* flow, and that it is the very force of the retrograde movement which maintains the open door of the arterial channels.

In the course of an ordinary blood-pressure estimation, so brief is the period of Stage II and so slight are the forces engaged (a few millimetres of mercury measuring the effective surplus pressure), it is probable that the naked eye would not recognize any change in calibre of the brachial artery and its chief branchings, even at the conclusion of this stage. But if it were possible to call in the microscope to our aid and bring it to bear on the peripheral capillaries of the isolated blood mass instead of the main trunk—what then?

It is just here that Professor Hill's evidence comes in respecting the minute movements of the blood in the web of the frog's foot, under conditions which reproduce those which the sphygmomanometer imposes. For he shows, in the first place, the presence of an isolated—that is, *imprisoned*—mass of blood; and, secondly, he shows it in process of evacuation by a *reversed* flow; it is this reversed flow which proves the isolation, since it points to closed veins. All this takes place under a rising extravascular pressure. Here are his words, after describing how, under the increasing pressure, first one capillary loop is emptied, then another: "If the pressure be now raised further the flow ceases in more and more capillaries and venules, and finally in all, and in the arterioles." A little further on he says: "During the expression and blanching of the web the flow in the arterioles is reversed." *But this reversed flow is proof positive of open arterial channels*; it would be impossible with an obliterated main artery.

Need I say more? I craved the *visio oculorum* of Bacon—it seems to me that Professor Hill meets my desire.

In conclusion, may I appeal to my colleagues—physiologists and physicians—in the name of *science to look* into this matter, which is and should be entirely impersonal. I am convinced that a sectional obliteration of the trunk of the brachial as at present held and taught is wholly untenable, but my argument may be at fault. Is it too much to ask that it be examined? I would repeat here that the question of the patency of the arteries raises a definite practical issue.—I am, etc.,

London, March 19th. HARRINGTON SAINSBURY.

SIR,—In the discussion on this subject Dr. Harrington Sainsbury, Sir James Barr, and Dr. Leonard Hill do not mention the simplest and surest way of *seeing* by means of the ophthalmoscope what happens to the compressed artery.

If the arterial pulse is produced on the disc by finger pressure, or by the dynamometer of Baillart, the observer will see the arteries collapsed and refilling with blood only when the systolic wave is entering them. By increasing the pressure still more the arteries will be seen to remain collapsed and empty all the time, as the systolic wave will not be able to enter them. The same applies to the retinal veins, but the necessary pressure on the eyeball is, of course, a very slight one. The colloids of the eye are even more incompressible to a certain degree than those of the hand, because they are surrounded by a rigid sclera.

It is, in my opinion, the best proof that the portion of the artery does collapse and remains empty under a pressure locally applied and higher than the systolic one.—I am, etc.,

London, E.1, March 8th. N. PINES, M.B.

EFFECT OF OBSTRUCTED RESPIRATION ON HEART AND LUNGS.

SIR,—The interesting paper by Drs. Crowden and Harris in your issue of March 9th (p. 439) raises several points of importance to the practising radiologist. Their statement that the ideal radiograph of the chest requires an exposure of one-hundredth to one-sixtieth of a second is correct, but this exposure is by no means outside the range of most hospital *x*-ray equipments. At a distance of 30 inches with a 10 kw. transformer and any type of tube it is a comparatively simple procedure to photograph a chest in one-sixtieth of a second. At 2 metres distance it is less easy, and requires a tube capable of standing a very heavy load. There are many such tubes on the market to-day. In both instances, however, it is necessary to use a hard ray, and the resulting picture is by no means ideal.

Experiments, spread over several years at the Royal Chest Hospital, with the object of discovering the ideal chest radiograph, have led to the following conclusions. The ideal chest radiograph should show: (*a*) the heart outlines clearly and sharply; (*b*) the superior vena cava; (*c*) one or both subclavian arteries; and (*d*) the normal interlobar pleura between the right upper and middle lobes. On such a picture it is possible largely to differentiate between the vascular and bronchial markings in the lungs, and, more important still, the earliest focus of tuberculosis will be visible.

A radiograph fulfilling these criteria can be obtained by employing the following technique. The photograph is taken in the erect position at 2 metres distance. The exposure, made during moderate inspiration, is one-twenty-fifth of a second, the voltage 55 kv. effective, and the milliamperage 150 to 160. The tube is of the line focus type.

This technique is also the correct one for obtaining accurate heart measurements; the phase of the cardiac cycle during which the exposure is made causes only a negligible increase in the radiographic size of the heart, which can be checked. The size of the heart can always be checked by comparing its total width with the total width of the chest. The ratio, which is constant in health, is 1 to 1.9 in females and children, and 1 to 2 in males.

Drs. Crowden and Harris are apparently unaware of this factor, known as the heart-lung coefficient, and appear to think that the terms "dilated heart," "peribronchial fibrosis," and "increased hilum shadow" are the unscientific jargon of the radiologist which "may have to be abandoned." These terms have been abandoned for many years by radiologists with "chest" experience. The term "increased hilum shadow" indicates poor technique, for the separate structures forming the hilum are all visible on a good picture. Peribronchial fibrosis is now diagnosed only when it is present, which is rare, except in certain forms of phthisis.

Examination of 8,000 chests in the erect position has not, in the Royal Chest Hospital, been followed by one case of either dizziness or fainting. The ventilation of the authors' *x*-ray room or perhaps an uncomfortable position for their patients in the apparatus may be responsible for the malaise so lightly attributed to the influence of respiration on the circulation.—I am, etc.,

London, W.1, March 12th. PETER KERLEY.

UNIVERSITY OF LONDON PARLIAMENTARY REPRESENTATION.

SIR,—A note in the *Journal* of March 23rd (p. 581) states that three members of the University of London Conservative and Unionist Association executive are prepared to support Dr. E. Graham Little in his independent candidature at the forthcoming General Election. As this statement is inaccurate, perhaps you will allow me to say that the president, fourteen vice-presidents, every one of the eleven members of the executive committee, and the two honorary secretaries of the association, totalling twenty-eight persons, are opposed to the return of Dr. Graham Little, and for the following among other cogent reasons:

1. In 1924 Dr. Little, at the instance of a non-political body of graduates, saw fit to oppose the constitutionally selected candidate, Sir John Rose Bradford, K.C.M.G., since elected President of the Royal College of Physicians of London, and this *after* he had given a written statement that he would support Sir John.

2. In that year he stood as an Independent, was elected as an Independent by the narrow majority of 389 over Sir John Rose Bradford, has sat in the House as an Independent, and must stand again as an Independent.

3. It was as an Independent that he moved the rejection of the Government's University of London Bill, his motion being negatived without a division. This tends to prove as true what appeared in your issue of January 5th, 1929 (*Supplement*, p. 5): "an 'independent M.P.' does not exert much influence in the House. . . . He is ignored by the Whips, and can rarely influence the House . . ." concerning the value of an independent member of the House of Commons.

4. Dr. Graham Little has derided the scheme of Lord Dawson for the co-ordination of medical services on more than one occasion.

5. He has opposed the scheme of the British Medical Association for the same, and when he seconded, at the Representative Meeting at Cardiff in July, 1928, an amendment which had the promise of wrecking the whole scheme, this amendment was lost by an absolutely crushing majority.

It should be known to all medical graduates of the University of London that the Conservative and Unionist Association of the University in general meeting duly summoned has in a manner constitutional selected as the prospective candidate at the forthcoming General Election Sir John Gilbert, K.B.E., B.A., a member of the Senate of the University, and a late chairman of the London County Council, and that this selection carries with it the full support of the Conservative and Unionist Central Office.

It is understood that there will be a Liberal candidate, and probably other independent candidates besides Dr. Little, but the seat cannot be lost to the Conservative party, as asserted by Dr. Little's supporters, but can be regained for the party if all Conservative graduates vote for Sir John Gilbert.—I am, etc.,

W. MCADAM ECCLES,
Chairman, University of London Conservative and Unionist Association.

March 25th.

OPPORTUNITIES FOR MEDICAL WOMEN IN CANADA.

SIR,—In the notice of the meeting of the Medical Women's Federation, in your issue of March 16th (p. 507), I am reported as saying that the opportunities for gynaecological practice in Alberta, Canada, were "very good" for medical women.

I did not say this, but only that those who had started by working in the more remote country districts might later find opportunities in the smaller, but growing, towns. I further suggested that anyone contemplating private practice should first inquire of the secretary, Alberta Medical Association, as to the possibilities before going out.—I am, etc.,

E. M. JOHNSTONE.

West Clandon, March 25th.

Obituary.

A. E. CUMBERBATCH, M.B., F.R.C.S.,

Consulting Aural Surgeon, St. Bartholomew's Hospital.

WE regret to record the death, on March 25th, at the age of 82, of Mr. A. E. Cumberbatch, whose long life was spent almost entirely in the service of medicine. We are indebted to Mr. L. A. Lawrence for the following particulars.

Cumberbatch was a Bart's man, and during his studentship at the hospital won the Kirkes gold medal. In 1870 he obtained the diploma M.R.C.S., and in the following year graduated M.B.Lond.; in 1872 he became F.R.C.S. He held the usual house appointments, and was, I believe, house-surgeon to Sir William Savory, after which he transferred to the dissecting rooms as demonstrator of anatomy. He was well qualified for the post, as he had a most intimate knowledge of this subject. It was a pleasure to be helped by him, and he gave of his best. The little leisure from the "rooms" was spent in helping John Langton, who was in charge of "ears." In 1882 the demonstratorship in ears held by Langton was promoted to a special department and placed under the care of Cumberbatch, who had resigned the "rooms." He was the first man who was not on the medical or surgical staff and yet was placed in full charge of a special department.

He had to do practically all the work himself, but was occasionally helped by someone who took an interest in ears. The department was held in a corner of the large general surgery, partitioned off on ear days. The partitions did not cut off the usual noises of a large surgery. The work was done standing. There were only two lamps and two wash-basins. In this place Cumberbatch contrived to see all the patients and to instruct the few students who came to learn. In after years dressers were added to the department. The new buildings at the hospital brought new vigour to the ear department, and Cumberbatch was given permanent assistance, which enabled him to devote more time to teaching. He resigned the appointment in 1908, and was made consulting aural surgeon and a governor of the hospital. The war brought him back to active work in the ear department. He was also aural surgeon to the National Hospital, Queen Square. His large private practice occupied him very fully till the last few years, when he retired to Sarratt in Hertfordshire, where he died.

Cumberbatch had many hobbies; he played a creditable game of tennis, and was a good billiard player. That lightness of touch which he showed in the dissecting rooms and the operating theatre stood him in good stead here. He loved golf, and was very keen about it till old age got the better. Many stories could be told of him on the links. One of his curious ways was to putt with a driver, and to putt well, too—all due to his deft hands. He was a collector of many things, among them stamps and oriental porcelain; he was somewhat of an authority on both.

Cumberbatch was not a voluminous writer. *Waldham's Surgery* owes something to him. He was one of the founders of the Otological Society of Great Britain and Ireland, and its treasurer at one time, and also its president. He took an active part in the International Otological Congress held in London in 1899.

JOSEPH RODERICK SUTHERLAND, M.B., Ch.B.,

Superintendent, County Orthopaedic Hospital, Stonehouse.

BY the death of Dr. J. R. Sutherland, superintendent of the County Orthopaedic Hospital, Stonehouse, Lanarkshire has lost one of its ablest and best-known physicians. Joseph Roderick Sutherland was educated at the Glasgow High School and later at Glasgow University, where he received his medical education and graduated M.B., Ch.B. in 1905. In 1907 he obtained the diplomas M.R.C.S.Eng. and L.R.C.P.Lond., D.P.H.Camb. in 1912, and B.Sc. (Public Health) Glasgow in 1914. After holding resident posts at the Blackburn Infirmary, the Royal Infirmary, Glasgow, Glasgow Maternity Hospital, the Glasgow Eye Infirmary, and Woodilee Asylum, and a post as assistant bacteriologist to the Corporation of Glasgow, he was in

1912 appointed medical superintendent of the County Sanatorium, Stonehouse. Following a period of war service in France he returned to tuberculosis work, and after a long struggle helped to make the County of Lanark Orthopaedic Hospital one of the foremost institutions of its kind in the country. Sutherland possessed a retentive memory and an alert analytical mind, and his wide and varied knowledge of English literature and art made him a delightful companion. He was a fine yachtsman, and used to spend his vacations exploring the lochs of the West Highlands. His funeral, attended by representatives of all classes of the community, was evidence of the affection and esteem in which he was held.

A colleague writes: The passing of Dr. Joseph Sutherland is a sad event for those whose privilege it was to know him personally. His death, at the comparatively early age of 46, when, it might be said, only half his useful life had been spent, creates a gap in the ranks of the skilled orthopaedic surgeon which it will be difficult to fill. During his tenure of office at Stonehouse, Dr. Sutherland applied himself devotedly to the care of the cripple from surgical tuberculosis, and sometimes from very unpromising human material obtained very good results. He had a genius for "construction," and this was shown in plaster and celluloid work of the highest order. Not infrequently he spent his holidays visiting English and Continental centres in order to keep himself abreast of the times, and he followed the literature closely. Stonehouse was a resort to which fellow workers came to see Sutherland's methods. He was adored by his patients, and relatives put implicit and well-founded faith in him.

The following well-known foreign medical men have recently died: Professor DOMENICO BARDUZZI, formerly director of the clinic of dermatology and syphilology at Siena; Professor DOMENICO MAJOCCHI formerly director of the clinic of dermatology and syphilis at Bologna; Professor ERNESTO TRICOMI, director of the surgical clinic at Bologna, aged 70; Dr. VALENTINO GRANDIS, professor of physiology at Genoa; Professor H. DREESEMANN, a Düsseldorf surgeon; Dr. MAXIMOW, professor of normal anatomy at Chicago and an eminent histologist, aged 54; and Dr. MANUEL QUINTELA, professor of oto-rhino-laryngology in the University of Montevideo, aged 63.

Universities and Colleges.

UNIVERSITY OF LONDON.

COURSE IN MENTAL DEFICIENCY.

A COURSE of lectures for medical practitioners on mental deficiency and other mental conditions closely allied to it, supplemented by a course of clinical instruction, has been arranged by the University Extension Board in co-operation with the Central Association for Mental Welfare. The course is divided into Parts I and II. the first starting on May 27th and closing on June 1st and the second commencing on June 3rd and terminating on June 8th. The whole course may be taken, or the two parts taken separately. There is a registration fee of 10s. 6d.; the fee for the whole course is £5 5s., or £3 3s. for each part. The course is based on the requirements for the University of London diploma in psychological medicine, and is intended for qualified practitioners, more especially for those engaged as school medical officers, certifying officers to local authorities under the Mental Deficiency Acts, or as medical officers of institutions. All communications with reference to the course should be addressed to Miss Evelyn Fox, care of *University Extension* Department, University of London, South Kensington, S.W.7.

UNIVERSITY OF DURHAM.

AT the convocation held on March 22nd the following degrees were conferred:

M.B., B.S.—A. Davis, Katharine M. Girling, J. A. Lennox, D. C. Livingston, W. Mair, J. H. F. Pankhurst, J. H. Pool, J. W. M. Stevenson, H. Wilcox.

UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examination indicated:

D.P.H.—*Part II*: A. Anderson, Helen G. M. Bennett, Mary Evans, J. J. O'Reilly, Mary I. Prentice, Marjorie Reekie, Kathleen Sheehan.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—*F. R. Anderson, Ida E. Ashby, P. Barr, Jean M. Barrowman, R. S. P. Begg, R. P. Boyd, W. P. Brown, A. M. Campbell, Ellen J. R. Campbell, L. S. Campbell, D. T. Clark, W. A. Clark, J. S. Craig, T. Dunlop, J. Fairey, R. Forrest, Isobel C. Fraser, P. A. Gallon, W. S. Gardner, Annie R. Greig, T. M. Hamilie, D. L. Henderson, H. W. Laing, J. W. Laird, L. W. Laurenson, R. H. Leishman, D. C. Liddle, J. H. M'Broom, D. R. M'Calman, W. D. C. M'Crorie, J. M'Michael, W. J. M'Neish, Georgina A. M'Nicol, A. F. Maguire, J. L. Mayer, T. R. Murray, A. J. Neirn, Mary S. Nicholson, J. P. O'Hear, Jean B. Parker, T. F. Rodger, †M. M. Scott, J. G. Simon, W. Smith, J. Stewart, J. Taylor, H. R. Weir, *A. T. Wilson, H. Wyers, *†A. M. Willie.

* Distinction in surgery. † Distinction in medicine.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A MEETING of the Royal College of Physicians of London was held on March 25th.

Sir John Rose Bradford, K.C.M.G., C.B., M.D., F.R.S., was re-elected President.

Dr. J. W. Carr was appointed a representative of the College on the Professional Classes Aid Council.

Diplomas in Tropical Medicine and Hygiene and in Ophthalmic Medicine and Surgery were granted jointly with the Royal College of Surgeons to 44 and 25 candidates respectively. (The names of the successful candidates were published in the report of the meeting of the Royal College of Surgeons of England printed in our issue of March 23rd, page 581.)

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—K. Girgis (Section II), D. H. Haler, H. H. Lakin, A. W. Tam.
MEDICINE.—A. Clark, J. M. Connor, R. W. Goldsbrough, R. W. Scanlon.
FORENSIC MEDICINE.—R. W. Goldsbrough, R. K. Nandlal, K. M. Seedat.
MIDWIFERY.—I. M. Idda i V. R. D. Lahammi, J. E. Moody, Z. Risk, A. W. Tam, E. O. Watson.

The diploma of the Society has been granted to Messrs. J. M. Connor, K. Girgis, D. H. Haler, and R. W. Scanlon.

The Services.

DEATHS IN THE SERVICES.

Fleet Surgeon James William Hambly Hawton, R.N. (ret.), died at Plymouth on March 19th, aged 78. After qualifying M.R.C.S. and L.S.A. in 1875, he entered the navy as surgeon on March 31st, 1874, became staff surgeon in 1886, and fleet surgeon in 1894, retiring in the following year. His last ship was H.M.S. *Edgar*, in China, in 1893–95.

Colonel Bernard James Newmarch, C.M.G., C.B.E., Australian Army Medical Corps (ret.), died recently at Sydney, aged 72. He was educated at King's College Hospital, qualifying M.R.C.S.Eng. in 1877, L.R.C.P.Lond. in 1881, and took the F.R.C.S.I. in 1903. After qualifying he held posts as house-surgeon and surgical registrar to King's College Hospital, and as medical superintendent of the Royal Free Hospital. After some ten years in London he went to Australia, and settled at Sydney, where he held the appointments of surgeon to the Sydney Hospital and to the Royal North Shore Hospital at Sydney. He served as a subaltern in the New South Wales contingent in the South African war, and rose to the rank of captain. At the beginning of the great war he was lieutenant-colonel commanding the 1st Field Ambulance of the Australian Army Medical Corps, and came to Europe with that unit. Later he commanded the 1st, and afterwards the 3rd, Australian General Hospital; he was promoted to the rank of colonel in 1917, and served at headquarters in London in 1917–19.

Lieut.-Colonel Thomas Samuel Lloyd-Barrow, R.A.M.C. (ret.), died at Weymouth in February, aged 86. He was born in London, on May 17th, 1842, the son of Inspector-General T. W. Barrow, A.M.D., was educated at St. George's, taking the M.D. at St. Andrews in 1862, and the M.R.C.S. and L.S.A. in 1863, and entered the army as assistant surgeon on March 31st, 1864. In the old regimental days he served in the 23rd Foot, now the Royal Welch Fusiliers, and in the 3rd Dragoon Guards. He became surgeon major on April 23th, 1876, and retired, *with an honorary step, as brigade surgeon*, on April 23rd, 1884. He took the additional name of Lloyd in 1881. He saw his first active service in the Kaffir war of 1851–52, at the early age of 9. He had accompanied his parents to the Cape, and was beleaguered in a frontier fort, garrisoned by the 2nd Foot, the Queen's West Surrey Regiment, with his father, for nine months. He again saw foreign, though not active, service with his father in Canada, in 1859–60. While in the army he served in the Egyptian war of 1882, was present at the battle of Tel-el-Kebir, and received the Egyptian medal and the Khedive's bronze star. He also received the thanks of the general commanding at Gibraltar, and of the director-general, A.M.D., for his services in a cholera epidemic at Gibraltar in 1865. He was a J.P. for Brecknock county. His family have contributed many officers to the A.M.D. and R.A.M.C. Besides his father and himself, his younger brothers, Lieut.-Colonel F. E. Barrow and Colonel H. J. W. Barrow, served in the R.A.M.C., and the last was the father of Major-General H. P. W. Barrow, C.M.G., D.S.O., A.M.S. He married Miss Bevan of Brecon, who in 1911, leaving two sons.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

PARLIAMENT stands adjourned for the Easter recess. Before it rose, on March 27th, the Royal Assent was signified to the Local Government Act, 1929, for England and Wales, and to the Factory and Workshops (Cotton Cloth Factories) Act, as well as a number of Acts confirming provisional orders of the Ministry of Health. When the House of Commons reassembles, on April 15th, Mr. Churchill will introduce his Budget.

The prorogation of Parliament is commonly anticipated about Whitsuntide, and the dissolution will follow without delay.

Local Government (Scotland) Bill.

On March 26th the House of Lords was in committee on the Local Government (Scotland) Bill. Amendments to preserve the autonomy of the smaller burghs were defeated. One of these amendments proposed to raise to the status of a large burgh any burgh which, during the summer months, had a population in excess of 20,000. In resisting this amendment Lord AIRLIE, for the Government, said burghs did not have to provide for summer visitors the benefits of lunacy and mental deficiency services, nor even of public health services, since most epidemics were in the winter. Maternity and child welfare services also were not provided for summer visitors.

Clause 11 provides for the combination of two or more authorities if a district asylum or institution for mental defectives has been provided by a district board of control, whose functions under the bill are transferred to such authorities. Lord AIRLIE moved an amendment which would waive the obligation for combination if the authorities concerned and the General Board of Control for Scotland agreed otherwise. He said this was to meet the case of Paisley, where the parish council, which was also the board of control, had provided an asylum for the burgh of Paisley and for that small portion of Paisley parish which was in the county of Renfrew outside the burgh. The amendment would allow Paisley town council to buy out the interests of Renfrew county council in the asylum and run it exclusively for the burgh. The amendment was accepted.

In Clause 14, which deals with the preparation of administrative schemes by county councils, Lord AIRLIE moved to omit lunatics from the classes of persons for whose maintenance and treatment the scheme might provide by way of poor relief or by virtue of enactments other than the Poor Law Acts. He said that treatment of lunatics was provided under the Lunacy Acts and not under the Poor Law Acts. The House agreed to the deletion.

Clause 35 proposes that, unless the Department of Health otherwise agrees, the county medical officer of health shall become the health officer of any small burgh where that post falls vacant. Lord YOUNGER OF LECKIE moved an amended form of words regarding the appointment of the county medical officer and of the county sanitary inspector when vacancies occurred in similar posts in small burghs. He said it was desirable that the sanitary inspector should be under the orders of the county medical officer of health. Lord SALISBURY resisted the amendment, contending that the Secretary for Scotland should be left a discretion. Lord YOUNGER withdrew his amendment.

After other amendments had been discussed the bill passed through committee.

Treatment of Rheumatic Insured Persons and Children.—Mr. CHAMBERLAIN, replying to Brigadier-General Wright, on March 25th, said that all insured persons in Great Britain (with the almost negligible exception of voluntary contributors with an income exceeding £250 a year) were entitled to medical treatment. Under that benefit insured persons suffering from any form of rheumatism were entitled to receive from insurance practitioners such treatment as the practitioners considered to be proper and necessary, except treatment involving the application of special skill and experience of a degree or kind which general practitioners as a class could not reasonably be expected to possess. Further, if an insured person was a member of an approved society which had adopted additional benefit No. 10, and if that person received treatment as an in-patient of a hospital, the society might make payment towards the cost of his maintenance and treatment. As soon as suitable arrangements could be made under additional benefits Nos. 8 and 16, it would be open to societies to make payment towards the cost of any special form of treatment of rheumatism, either by a registered medical practitioner in accordance with an approved special scheme or through the agency of an approved charitable institution. On the same day Mr. CHAMBERLAIN told Brigadier-General Wright that no complete particulars were available to show what hospital accommodation had been set aside in the last twelve months for the treatment of acute rheumatism among children. For London, the Metropolitan Asylums Board had, during 1928, set aside 38 additional beds in their institutions for the treatment of rheumatic affections among children (including rheumatic fever, acute endocarditis, and chorea). The total number of beds provided by the Board for this purpose was 170 at the beginning of the present month, and they were providing 350 additional beds in buildings now in construction. Accommodation was also provided for children suffering from rheumatism in other hospitals, institutions, and schools for physically defective children recognized by the Board of Education, but the exact number of beds so provided was not available.

Preservation of Infant Life Bill.—This bill, which has already passed the Lords, was read a second time without debate in the House of Commons on March 25th and sent to a standing committee.

Lepers in India.—On March 25th Earl WINTERTON, replying to Sir R. Thomas, stated that the number of persons in India returned as lepers at the census of 1921 was 102,513, but it was probable that the real total was considerably in excess of that. Information was not available on the number of treatment centres now open in India. As public health was a transferred provincial subject, the matter was one for the local Governments and legislative councils. The Indian Council of the British Empire Leprosy Relief Association worked in co-operation with the provincial Governments and voluntary agencies, and in each province the local Governments either supported leper institutions or made a capitation grant to institutions under the administration of the Mission to Lepers. The Secretary for India had a distinguished medical adviser at the India Office, who was closely associated with the new remedy for leprosy.

"Cancer Cures."—Sir KINGSLEY WOOD told Viscount Sandon, on March 25th, that the Cardigan alleged cure for cancer was one of several alleged cancer cures regarding which the Minister of Health had made inquiries through the Departmental Committee on Cancer. No information of scientific value was obtained by those inquiries, and no report had been made dealing with the "cure."

Deaths in Oldchurch Hospital, Romford.—Mr. CHAMBERLAIN, replying on March 25th to Mr. March, said he had seen a report by the medical superintendent of the Oldchurch Hospital, Romford, that nearly a hundred deaths occurred there within three weeks, and that many of the lives might have been saved if it were not for overcrowding. In the report this officer stated that some of the deaths which occurred in February could have been avoided had the guardians taken some notice of his repeated advice with regard to the lack of accommodation. Proposals for the increased accommodation for cases of tuberculosis were submitted by the guardians in August of last year. After consultation with the Essex County Council Mr. Chamberlain had come to the conclusion that the provision of additional wards of the ordinary hospital type was necessary, and the guardians themselves adopted this view in a letter addressed to him on January 14th, when they made proposals for extensions. Arrangements had now been made for the immediate discussion of the necessary plans between the guardians' advisers and his officers. There had been no delay on his part in dealing with any proposals from the guardians.

Deaths due to Gas Poisoning.—Sir P. CUNLIFFE-LISTER, on March 26th, told Mr. Bowerman that his attention had been drawn to the fact that in the past fifteen years deaths due to gas poisoning had increased from 170 to 1,142; since the report of the Committee on Carbon Monoxide in 1921 the situation had been watched and relevant information collected. Of deaths due to gas poisoning, a large proportion were cases of suicide. He thought that a small but experienced committee should review the developments which had taken place since the Pearce Committee sat in 1921, and he proposed to appoint such a committee. Replying to a question by Mr. W. Thorne, Sir P. CUNLIFFE-LISTER said that in 1927 the number of suicides from gas poisoning was 943, and the other deaths from the same cause 150. He proposed to appoint the committee within a reasonable time.

London Lock Hospital.—Asked by Major Astor, on March 28th, what changes of administration he proposed as the result of the report of the committee of inquiry into the London Lock Hospital, Sir KINGSLEY WOOD replied that the hospital was a voluntary institution and responsibility for carrying out the recommendations of the committee rested not with Mr. Chamberlain but with the board of the hospital. Mr. Chamberlain had not yet received specific proposals from the board for its reconstitution, but he understood that it contemplated the inclusion of women on the board in future.

Radium.—Sir KINGSLEY WOOD, replying to Lieutenant Commander Kenworthy, on March 25th, said that the report of the subcommittee of the Committee of Civil Research on Radium and Radium Supplies had been received, and would be published in full shortly. A statement of the intentions of the Government in the matter would be made on the reassembling of Parliament.

Social Hygiene Propaganda.—In an answer given on March 27th to Captain Crookshank, Mr. AMERY said that a grant of £500 had been made to the British Social Hygiene Council to assist in organizing propaganda work in the colonies and elsewhere. The employment of this money was limited to specified services, such as the supply of films and of medical and educational literature. Payments out of the grant were only made to reimburse certified expenditure on these approved services. The grant had not been discussed with the Ministry of Health, which had no responsibility for such work in the colonies.

Notes in Brief.

At the end of 1928 the number of persons insured in Great Britain under the National Health Insurance Act was estimated to be 11,550,000 men and 5,400,000 women. These included 720,000 persons who, having reached 65 years of age, have ceased to be entitled to sickness and disablement benefit.

Mr. Herbert Williams states that, whereas before the war nine-tenths of the glass used in British optical instruments was of foreign manufacture, the same percentage of the glass now so used was British.

Medico-Legal.

ACQUITTAL OF MEDICAL MAN ON MANSLAUGHTER CHARGE.

AT the Central Criminal Court, on March 27th, the jury, without leaving the box, found Dr. Daniel Evans Powell of High Street, Tooting, not guilty on an indictment charging him with the manslaughter of Mrs. Doris Ruth Simmons, and with intent to procure her miscarriage by an instrument or other means.

Mrs. Simmons died in St. James's Hospital on December 13th, and a *post-mortem* examination was made next day by Sir Bernard Spilsbury, in whose opinion an instrument had been used by a skilled person on or about November 23rd, leading to a septic abortion followed by inflammation of the kidneys and general septicaemia.

Dr. Powell, who pleaded not guilty and gave evidence on his own behalf, was defended by Sir Patrick Hastings, K.C., Mr. St. John Hutchinson, and Mr. John Maude. Mr. Eustace Fulton and Mr. Gerald Dodson represented the Director of Public Prosecutions.

Dr. F. J. McCann and Dr. Donald Roy, giving evidence for the defence, expressed the view that the circumstances leading to Mrs. Simmons's death were as consistent with natural causes as with the use of an instrument.

Mr. Justice Hawke, in his summing-up, referred to a complaint made by the defence that Dr. Powell had not been given an opportunity of being represented at the *post-mortem* examination; Sir Bernard Spilsbury's statement suggested to his lordship, however, that the coroner and not the police was responsible for this.

Medical News.

THE PRINCE OF WALES has accepted the invitation of the president, Sir Arthur Stanley, to become patron of the British Hospitals Association.

THE annual meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, W.1, on April 18th at 5 p.m., when the annual report and financial statement will be presented and the officers and committee elected for the current year.

THE following Chadwick Public Lectures have been arranged for this month and next. On Thursday, April 11th, at 5.30 p.m., Dr. J. F. C. Haslam will lecture at the Royal Sanitary Institute on "Health in British Guiana and the West Indies." On Tuesday, April 23rd, at 8 p.m., Mr. C. E. Stromeyer will Lecture at the Institution of Mechanical Engineers on "What health and civilization owe to engineering." On Thursday, May 16th, at 5.15 p.m., at the Royal Society of Arts, Sir Norman Walker will give the Malcolm Morris Memorial Lecture on "The progress of dermatology over 50 years." On Thursday, May 30th, at 5 p.m., Mr. H. V. Taylor will lecture at the Chelsea Physic Garden on "Supplies from the vegetable kingdom and the public health." Admission to these lectures is free and no tickets are required.

DR. HARRY CAMPBELL will give a lecture, under the auspices of the Food Education Society, on "Common errors in diet" on Wednesday, April 10th, at 3 p.m., at 29, Gordon Square, W.C.

A SPECIAL course of lectures and demonstrations in infants' diseases, for medical officers of welfare centres and others, will be held daily from 2 to 5 o'clock at the Infants Hospital, Vincent Square, Westminster, from May 27th to June 9th. The number attending the course will be limited to fifteen, and the fee will be three guineas. Further particulars can be obtained from the secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE University College Committee will award in June, 1929, a Bayliss-Starling memorial scholarship of the value of about £120 (with exemption from tuition fees). The scholarship will be tenable for the session October, 1929, to July, 1930; it may be renewed by the College Committee for a second and for a third year in exceptional circumstances. Candidates must be graduates or undergraduates of the University of London or any other university approved by the College Committee for the purpose, and of suitable standing in science or medicine. The scholar will be required to follow a course of study approved by the Jodrell Professor of Physiology involving a training in the principles and methods of research in physiology and/or biochemistry. He will be exempted from tuition fees in following such a course of study, but he will be required to pay a registration fee, the Union Society subscription, and, if required by the College Committee, the cost of special apparatus and materials. Each candidate must submit to the Secretary of University College, Gower Street, W.C.1, on or before May 15th, a statement giving full particulars of his educational career and of his qualifications for entering on a course of training in the principles and methods of research.

THE Hutchinson triennial prize (value £60), open to full students of the London Hospital of not more than ten years' standing since registration as such, will be awarded in 1932 for the best dissertation on remote consequences of fracture of the spinal column. Dissertations must be delivered at the hospital not later than March 31st, 1932, and the award will be made within six months of this date. Further particulars may be obtained from the secretary, London Hospital Medical College, Whitechapel, E.

STEADY increase continues in the membership of the Pathological and Bacteriological Laboratory Assistants' Association, which now numbers over 500, and the annual report for 1927–28 points to a satisfactory extension of its activities in the form of lectures, demonstrations, and examinations. A new branch has been formed in Glasgow and a very successful conference was held at Cambridge last year. The lending library scheme enables members to borrow books at a nominal cost, and the employment bureau has again proved its usefulness, both to members desiring change of post and to employers requiring assistants. After three years as president Professor H. R. Dean has been succeeded by Professor W. W. C. Topley.

AMONG the medical congresses to be held during the year are: the third international congress of medicinal plants at Padua in the second half of June; the triennial congress of the International Society of Surgery at Warsaw, from July 22nd to 25th (further information can be obtained from the secretary, 72, Rue de la Loi, Brussels); the German orthopaedic congress at Munich on September 18th, when the chief subjects for discussion will be coxa vara and the end-results of congenital dislocation of the hip (further information can be obtained from the president, Professor Hoffmann, Karlstrasse 16, Munich); and the annual congress of the Italian Society of Hydrology and Climatology at Spezia from October 4th to 6th, under the presidency of Professor Devoto.

AN international medical congress on balneology and balneotherapeutics will be held in Carlsbad from September 15th to the 21st. Special facilities in connexion with railway travel and passport fees will be available. Further information may be obtained from Dr. Edgar Ganz, Carlsbad, Czechoslovakia.

WE have received the first issue of a new quarterly periodical entitled *Human Biology*, and described as a "record of research," which has been published in Baltimore under the editorial direction of Professor Raymond Pearl. The editorial board consists of distinguished scientists in European countries and Japan, as well as in the United States, and includes Professor Major Greenwood. The outlook of the new journal is indicated by the publication in its opening number of the first of a series of studies of the human constitution in its relation to disease, and articles on racial variations and mental capacity, the sex factor in infant mortality, biological philosophy and medicine, and persistent negro physical features. The journal may be obtained from Messrs. Warwick and York, East Centre Street, Baltimore, Maryland, the advance subscription-price being 5 dollars a year.

THE March issue of the *Deutsche Zeitschrift für Chirurgie* has been dedicated to General Karl Ritter von Seydel, honorary professor in the medical faculty of Munich University and an eminent military surgeon.

THE opening of the tenth Salon des Médecins, which was to have taken place on April 21st (*Journal*, January 26th, p. 183), has been postponed till May 26th. Further information can be obtained from the secretary, Dr. Paul Rabier, 84, Rue Lecourbe, Paris XV^e^.

IN the sixteenth annual report of St. Andrew's Hospital, Dollis Hill, N.W.2, which is under the care of the Sisters of Mercy and the trustees of the Diocese of Westminster, an appeal is made for assistance towards the cost of extension, estimated at £30,000, of which some £7,000 has already been received. Although the normal number of beds is fifty-two, the average number of patients resident daily throughout 1928 was fifty-nine, and many deserving cases had to be refused. A new ward pavilion is in course of erection; it will consist of two wards of twelve beds each and an operating theatre. The building of the nurses' home has also begun; when completed this building will release at least fifteen extra beds in small private rooms in the present hospital. Although there is no out-patients' department, it was necessary to deal with 304 accidents and other urgent cases during the year. Patients are received for treatment in the wards, cubicles, and private rooms without distinction as regards nationality or creed.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, *on receipt of proofs.*

All communications with reference to ADVERTISEMENTS, as well as *orders* for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

PROLONGED ADMINISTRATION OF CASCARA.

DR. L. J. HOBSON (*Harrogate*) writes: In reply to "Sigmoid's" inquiries (March 23rd, p. 584), I have taken, and also prescribed, cascara, as an extract, for some forty years for habitual constipation, and without any deleterious result at any period of its administration. Quite exceptionally, however, it has been withheld, owing to a history of some griping in its action. Otherwise the first condition insisted upon for its success has been a definite daily dosage of 4 grains in an adult at first, reducing to 3 grains, and in some cases to 2 grains, when this has at length proved a sufficient dose. I always give it in the form of the standardized tabloids, to be taken a few minutes before, and not after, the evening meal, which is the second cardinal condition to ensure a daily action on the morning following.

INCOME TAX.

"PERPLEXED" received from a patient a "gift of £100"; he had had to buy a house, and the cheque was given to assist him, as was explained in the donor's covering letter. Is this liable to income tax?

*** Gifts are not liable to income tax in the hands of the recipient; they are outside the scope of the tax. At the same time we should perhaps point out that if, when the gift was made, the patient in question had received professional attention for which a fee would ordinarily have been charged, but which was cancelled in the special circumstances, then it would seem reasonable for "Perplexed" to return for assessment a corresponding amount, as being in effect included in the £100 gift.

LETTERS, NOTES, ETC.

THE DOCTOR AND CHEMICAL WARFARE.

DR. ARTHUR T. JONES (Mountain Ash) writes with reference to Dr. Humphreys's letter on January 26th (p. 180): With the Covenant of the League of Nations and the Kellogg Pact, warfare of any kind, and especially chemical warfare, ought to be beyond the range of possibility. Such warfare, involving, as stated by Dr. Humphreys, the death of 5,000 in five minutes, is too horrible to contemplate, but poison gas let loose on a civil population or a whole community means nothing short of annihilation. Dr. Humphreys suggests that the British Medical Association should formulate some practical policy to meet the situation and to equip medical practitioners with antidotes for themselves and those in their care; I fear that, far from having an opportunity of exercising their skill or knowledge, they would probably all be huddled among the victims. Surely we should aim at something higher and more rational. If, as medical men, we believe that prevention is better than cure, we should act accordingly. It seems to me quite incongruous that, side by side with laboratories engaged in discovering the cause and cure of cancer and other scourges of mankind, others should be engaged in research designed to invent poison gases for chemical warfare. If there is any duty incumbent on us individually as medical practitioners, and collectively as an Association, it is that we should take the lead in creating public opinion for the prohibition of research in and manufacture of poison gas. Even if we cannot hope to abolish war completely, we should so foster this public opinion as to make it a potent factor in the enactment of international legislation, by which chemical warfare will be condemned as an illegal procedure.

UNUSUAL SYMPTOMS OF PROSTATE ENLARGEMENT.

DR. MARSHALL HAVER (Driffield) writes: Mr. Grey Turner's article of February 9th (p. 233) and "J. C.'s" note of March 23rd (p. 553) prompts me to send the following. Recently I had a very old patient, since dead, with prostate enlargement, who had used the catheter for five years. He often described to me a curious sensation he experienced in the soles of the feet occurring the instant micturition ceased. He had some difficulty in describing the sensation, but likened it to a feather lightly brushing and tickling the soles. The sensation was momentary and invariable, and amused him greatly. I have often wondered what reflex connexion there is between the bladder and the soles of the feet.

"AURIST" writes: I have similar symptoms to those mentioned by "J. C." (March 23rd, p. 584) when my bladder is distended, especially with pale urine of low specific gravity. I get neuralgic pains in the palms of the hands and fingers on urination.

ANAESTHESIA FOR COLLES'S FRACTURE.

DR. E. J. CHAMBERS (Doncaster) writes: I read the article on March 16th (p. 491) with surprise that Mr. Blundell Bankhart thinks so little of gas-oxygen anaesthesia, as carried out with an efficient machine. There is no "luck" about it; nor is there any difficulty in treating a Colles's fracture with the patient anaesthetized by this method, the safety of which is acknowledged by all. A deep chloroform or ether anaesthesia is certainly, in my opinion, subjecting the patient to unjustifiable risk and considerable avoidable discomfort.

QUININE IN INFLUENZA.

DR. A. H. DODD (Bournemouth) writes: During the earlier epidemics of influenza I was particularly sensitive and a frequent victim, necessitating many locums. On the advice of one who had himself been in practice for many years, I tried quinine as a prophylactic. Always afterwards in the late autumn, or at the slightest hint of return of an epidemic, I was in the habit of taking one or two grams of quinine sulphate (preferably sugar-coated pills or uncoated tabloids, both being so easily soluble and reliable) the first thing in the morning on rising, *with a tumbler of hot water.* I went eight years *without another attack*, then had a slight one, followed by another five years' freedom. I used to continue taking the quinine for about four to five months. I have frequently advised others to follow this line, and with great success when persevered with. In one boarding school, at my recommendation, the head mistress gave it to *all, and not* a single case of illness occurred during one of the severe epidemics.

THE USE OF THE TONSILS.

DR. J. MCNAMARA (London, W.) writes: In your issue of *March 23rd* (p. 543) Dr. *Irwin Moore* is quoted as stating that "the general opinion is that after the age of 5 years nearly all tonsils are useless and are in the majority of cases a menace to health." *That the ring of lymphatic tissue including the tonsils, with the lingual and pharyngeal tonsils, which, like a defensive bulwark, surrounds the entrance to the body, is useless after five years is a priori improbable.* I know two children who had their tonsils removed when well over 5 years old. One of these within a year, the other within a few years, developed an irregular rise of temperature, with chests shown by *x*-ray examination to be crowded with enlarged tuberculous glands. I cannot say whether the tuberculous infection of these glands after removal of the tonsils was *post hoc* or *propter hoc*, but the experience is suggestive, and if any readers have had a like experience its publication would be useful.

AN OPTICAL PHENOMENON.

DR. W. F. LLOYD (Windsor) writes: If an object such as an isolated pane of glass against a dull sky, or the disc of the moon, is looked at, first with one eye, and then with both, two changes are observed: the object becomes brighter and also larger. One might expect it to appear brighter, since the brain is receiving twice the amount of stimulation, but why does it seem larger? Is it that the images on the retinae do not quite correspond? In that case one would expect a hazy outline, but the outline seems to be quite definite. In my case the object seems to increase in size about one-twelfth of its diameter.

A DISCLAIMER.

DR. F. M. WALKER (Ayr) writes to state that the recent appearance of his name in a local newspaper in connexion with a case of blood transfusion was without his knowledge or approval.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 49, 50, 51, 52, 53, 55, and 57 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 82.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

331. Herpes Zoster and Tuberculosis.

A. WALLGREN (*Acta Paediatrica*, December 22nd, 1928, p. 241) believes that there is an association between herpes zoster, varicella, and tuberculosis. He agrees with other authors that the varicella may, in some cases, give rise to herpes zoster. He finds also that certain internal organs affected by tuberculosis may transmit to the spinal ganglia and their corresponding cutaneous zones a state of irritability which determines a local predisposition to herpes. His conclusions are based on the following clinical observations. On the same day two children, aged 3 and 5 years, in adjoining beds in a small ward reserved for tuberculous children, developed intercostal herpes zoster; in both cases the herpes was localized to the same side as the tuberculous bronchial glands, for which the children were being treated. At the end of a week varicella broke out in the remaining children in the ward who were not immune. It was thought that these two children had been subjected to an infection of varicella on the occasion of a visit to the light clinic, and the period of incubation corresponded with this supposition: the illness presented itself not as varicella, but as herpes zoster. The author suggests that the infective agent was fortified in the already predisposed spinal ganglia. The corresponding cutaneous segment reflected the attack on the spinal ganglia, thus producing a circumscribed eruption of varicella or herpes zoster, which, being provoked by the infective agent (varicella), might be expected to be as contagious as the malady itself. This proved to be the case, seeing that varicella developed in the other children though not in the two original children, who were not affected by the varicella to which their herpes had given rise.

332. Rheumatic Fever.

R. L. LEVY and K. B. TURNER (*Arch. Intern. Med.*, February, 1929, p. 267) present a comparative study, with diagnostic applications, of impaired auriculo-ventricular conduction in rheumatic fever as affording evidence of myocardial involvement. Of 145 cases showing disturbance in auriculo-ventricular conduction, more than half were instances of rheumatic fever; delayed conduction, as shown by the lengthening of the P–R interval, was the most important of these disturbances, and much more common than heart-block. The fact that such prolonged conduction is more frequent in rheumatic fever than in any other disease assists the differential diagnosis, since a prolonged P–R interval or heart-block occurring in a person under the age of 35, who is not syphilitic and who has not taken digitalis, affords presumptive evidence of the presence of rheumatic carditis; in rare instances heart-block may be the first sign of rheumatic fever. In the absence of other criteria the sign may be useful in establishing the rheumatic nature of a cardiac disturbance. The prolongation of conduction may persist and afford evidence of myocardial lesions in rheumatic fever long after the clinical manifestations have subsided. In rheumatic fever such disturbances in auriculo-ventricular conduction are usually transitory, but in arterio-sclerotic and hypertensive heart disease they tend to become permanent. In rheumatic fever the condition is usually accompanied by leucocytosis during the active stages of the disease, a long P–R interval and leucocytosis being signs of active infection of the heart muscle.

333. Purpura Haemorrhagica following Rubella.

T. PITTEN (*Arch. f. Kinderheilk.*, January 25th, 1929, p. 114) remarks that rubella is generally regarded as one of the mildest of all infectious diseases. Most German authorities deny that it has any complications at all, although American, English, and French writers have described numerous sequels, such as nephritis, arthritis, and nervous and psychical changes. Pitten now records the case of a girl, aged 9, in whom symptomatic purpura haemorrhagica occurred directly after the appearance of the rash of rubella, and was characterized by haemorrhage from the nose and mouth with a generalized petechial eruption. The diagnosis of Werlhof's disease was based on a thrombopenia of 120,000, a normal calcium content of the serum; normal coagulation time, a positive Rumpel-Leede sign, and the prolonged bleeding time of forty two minutes. The author adds that thrombopenia and prolonged bleeding time are by themselves such typical symptoms that they alone are sufficient to justify the diagnosis of Werlhof's disease. Rapid and complete recovery occurred without special treatment.

334. Prophylaxis against Whooping-cough.

F. V. BERNUTH (*Münch. med. Woch.*, January 18th, 1929, p. 96) advocates the use of a prophylactic vaccine which is prepared from several strains of the Bordet-Gengou bacillus. Among seventy children inoculated there were only four failures. The inoculations must be given early owing to the long incubation period of the disease—up to five weeks. The duration of the protection is relatively short, and a case is recorded of a child becoming reinfected four and a half months after the inoculation. The contents of six ampullae containing 10 to 100 million bacilli are administered at intervals of three to four days either subcutaneously or intramuscularly; in doubtful cases it is better to give too much rather than too little. As a prophylactic the vaccine is recommended for infirmaries; in practice it should be given to delicate children and infants, and in certain cases it may be employed therapeutically.

335. The Dick Test in the Chinese.

M. Y. DZEN (*Nat. Med. Journ. of China*, December, 1928, p. 362), in view of the fact that during the past two years scarlet fever has been very severe in and around Pekin, performed the Dick test on 646 unselected persons in that city and obtained positive reactions in 46.4 per cent., a figure closely resembling Liu's results obtained in Harbin (47.07 per cent.), though considerably higher than the average percentage obtained by other investigators (37.78). It was also found that the unusually high percentage of positive Dick reactions closely corresponded with the age distribution of scarlet fever patients admitted to the Metropolitan Isolation Hospital, Pekin, during the last ten years.

336. Influence of the Thymus on Blood Pressure.

F. BRANCACCIO (*Studium*, January 20th, 1929, p. 3) reports certain clinical experiences in the administration of endothymin to a dozen patients suffering from various diseases; he found that in every case a marked lowering of blood pressure followed. After giving 1 c.cm. the pulse followed the lowering of the blood pressure, becoming smaller, but after 2 c.cm., while there was a sharp fall of pressure, the pulse became full and frequent. This effect of endothymin was not affected by adrenaline, atropine, pituitrin, or endothyroidin.

Surgery.

337. Large Pyogenic Abscesses of the Lung.

DURING the past few years the subject of large pulmonary abscesses has received much attention, especially as a result of the war and of the epidemics of influenza. F. BEZANÇON and A. JACQUELIN (*Paris Méd.*, February 16th, 1929, p. 167) claim that they should be regarded as a clinical entity, and that x rays and bronchoscopy have shown that this type of abscess is neither so rare nor so fatal as had previously been thought. They recognize three main types: (1) the acute circumscribed, by far the most common; (2) the extensive and chronic, with successive attacks and frequently fatal; and (3) the extensive acute abscess with a tendency to diffuse necrosis, associated with high bacterial virulence, pneumonic in type and very fatal. The first recognizable sign of such an abscess is the expectoration of pus, examination of which is of prognostic value. The physical signs vary, and may indicate a cavity in the lung; sometimes a layer of fluid due to pleural effusion masks the deeper trouble. Often there is only dullness, and sometimes, in the deep central forms, signs are absent. X-ray examination usually shows one large abscess cavity, often partly filled with air; sometimes the cavities are double or multiple. This type of abscess generally clears up in from two to three months. The second or chronic type is distinguished by the failure of medical treatment, a history of repeated attacks of bronchitis, and the insidious onset. The sputum is more frothy and mucous, dyspnoea is more marked, and cough is a more important feature. Radiography shows several abscess cavities, often in cluster formation. Pleural adhesions and contracting fibrous bands are the rule, so that pneumothorax is likely to be ineffective, and thoracotomy must be considered preferable. The general signs of this type are successive attacks of pyrexia, coughing, and increased expectoration, often accompanied by haemoptysis. The patient becomes emaciated slowly, and this variety may be termed pseudo-tuberculous. The third type is rare, a

is usually caused by the pneumobacillus and the streptococcus. Clinically and anatomically it is a massive necrosis of lung tissue, beginning with a pneumonic invasion and followed by necrotic disintegration. The duration of the illness is from five to eight days. As regards the prognosis, pneumococcal abscesses tend to end in spontaneous cure; streptococcal abscesses sometimes clear up remarkably quickly, but at other times lead on to chronicity or necrosis; while Friedländer's pneumobacillus causes the most serious conditions. The authors state that, owing to the chance of spontaneous cure in many cases, only medical remedies should be tried at first, such as eucalyptus or intravenous injections of urotropine. Serotherapy or autogenous vaccinotherapy are sometimes useful, and the thirst cure has given good results. Postural drainage has not been clearly successful in the authors' cases. The indications for surgical methods of treatment are discussed; first, pneumothorax, which, though often unsatisfactory, should be attempted. In certain cases phrenicectomy is useful, and in the chronic form, owing to the gravity and incurable nature of the disease, pneumotomy and thoracoplasty may be advisable.

338. Forage of the Prostate.

LE FUR (*Bull. et Mem. Soc. des Chir. de Paris*, February 1st, 1929, p. 89) gives details of the case of successful treatment of adenoma of the left lobe of the prostate of which a report appeared in the *British Medical Journal* on February 9th (p. 265). Two applications of electro-coagulation, according to the forage method of Luys, supplemented by vaccine therapy for the local and general state of infection, sufficed to effect cure. Le Fur discusses the indications for this line of treatment, of which the advisability turns on anatomical and clinical conditions. It is particularly indicated in cases of small, hard, sclerotic prostates, which include the following types: barred prostates with marked elevation of the vesical neck, due to mucous or muscular folds; atrophy and sclerosis with much vesical residue; and median lobes which form a lid over the neck of the bladder and block it during micturition. This treatment is also indicated for average-sized glands accompanied by urinary retention. Forage is markedly contraindicated in large prostates owing to its insufficiency, the danger of cauterizing through the great thickness of the lobes, the size of the sloughs, and the risks of haemorrhages and infection. Among the clinical indications is the amount of retained urine; Luys considers that a residue of 100 grams justifies forage. Le Fur, pointing out that the amount of troublesome retention varies greatly in different individuals, concludes that the method should be used only in patients with a certain degree of permanent retention, with marked troubles of micturition, and in whom medical and decongestive measures have failed. In advanced age forage is particularly indicated if the lesion is one of the before-mentioned types. Forage causes much less shock in these cases than prostatectomy. This operation is advantageous in young prostatics, since the glands are small and their enucleation is difficult. Other clinical indications for forage are patients with renal insufficiency, or in a bad general condition, and cystotomized patients with old hypogastric fistulas. Two methods of forage may be employed: the endo-urethral, and the suprapubic after cystotomy. All depends on the case; in simple lesions the former is preferable, and in median lobes and sclerotic barred cases the latter. High-frequency currents should be used; if the obstacle does not yield to a maximum of 500 to 600 m.a., resection should be employed. Le Fur emphasizes that forage and prostatectomy are not rival methods, and that each has its own indications.

339. Extra-articular Immobilization of the Hip-joint.

H. C. SCHUMM (*Surg., Gynecol. and Obstet.*, January, 1929, p. 112) describes an ileo-trochanteric strut-graft method for extra-articular immobilization of the hip-joint, which he has used in nine cases with uniformly successful results. The position of choice for fixation is a flexion of 20 degrees and an abduction of 10 degrees. Through a skin and fascial incision, commencing three inches behind and below the anterior superior iliac spine and carried downward over the great trochanter and side of the femur for about seven inches, the fibres of the gluteus medius and minimus are split and retracted so as to expose, without injuring the periosteum, the capsule of the joint and the surface of the ileum overlying it. By means of a 2-inch chisel large anterior and posterior flaps are raised from the great trochanter, each remaining attached to its base, and then with a 1-inch chisel a flap is raised from the ilium. The distance from the base of the ilial flap to the lower end of the trochanteric flaps is measured, and a graft is cut from the femur, beginning half an inch below the trochanter. The upper end of this is pushed up under the ilial flap, while the lower end is bedded in the trochanter, the flaps of which are sutured over it with catgut, and the fascial and skin incision closed. The patient is placed in a bivalved cast for about two months, after which the leg can be massaged daily; at the end of six or eight months all support can be removed, provided there are no *x*-ray or clinical objections. The chances of failure of fusion are minimized; the method has the advantage of simplicity, and requires only one incision. The presence of fistulae need not constitute a contraindication if the fistulous tract can be excluded from the field of operation.

340. Formation of a Gall-stone in the Stump of the Gall-bladder.

T. WALZBERG (*Med. Klinik*, February 1st, 1929, p. 184) refers to the uncertainty as to whether a stone found in the remnant of the gall-bladder after a previous cholecystectomy is a new formation or has been there before and been overlooked at operation. He reports a case in which the stone was certainly a new formation. In 1921 he operated on a woman, aged 62, on account of symptoms pointing to gall-stones. After separating many adhesions the gall-bladder was stripped back to the entrance of the cystic duct into the bile duct and shelled out subperitoneally; there was no spiral bending of the neck but a funnel-shaped widening of the cystic duct; this was cut and tied 1 cm. from the bile-duct, no stone being found in either the gall-bladder or bile-duct. For five years the patient was well, then in 1926 she had severe pain in the gall-bladder area; this recurred in 1928, when jaundice appeared. Since the temperature began to rise, it was decided to operate. A large oval stone 3.5 cm. long by 3 cm. round was found enclosed in a sac resembling the thickened fundus of a gall-bladder and containing a little thin bile. It had a smooth lining and appeared to be a new gall-bladder formed from the funnel-shaped stump of the cystic duct under pressure of the growing stone. It is known that a stone in the bile-duct may cause dilatation of the lumen and thickening of the wall, and it seems as if this had occurred in the stump of the cystic duct. Unfortunately the patient's condition necessitated quick closing of the abdomen; the sac was left behind and was not available for microscopic examination. The patient made a good recovery and has kept well so far.

Therapeutics.

341. Lead Treatment of Cancer.

A. SOILAND, W. E. COSTOLOW, and O. N. MELAND (*Journ. Amer. Med. Assoc.*, January 12th, 1929, p. 104) report the results of lead administration in cancer, a study begun two years ago. Their present technique is to inject 100 to 120 mg. of colloidal lead phosphate intravenously at weekly intervals until three injections have been given, when no more lead is administered for a period of from four to six weeks. No general reactions, except for an occasional chill due to the gelatin, were noted. The late effects occurring a few weeks after the lead had been administered were a sensation of weakness with anaemia and progressive deterioration. The local changes in the malignant tissues are said to be usually slow. The authors consider that irradiation should always be used in combination with the lead, and that the metal increases the sensitiveness to the ray treatment. Lead is considered as only one incident in the treatment, and the general nutrition must be maintained by a well-balanced diet rich in vitamins. Of 31 patients thus treated, 23 are reported as dead, 4 are failing rapidly, and only 4 are in good condition. The authors conclude that though the treatment has a temporary good effect these results are not encouraging, and that, when the expense is also considered, lead therapy does not appear to have solved the cancer problem. LEILA C. KNOX (ibid., p. 106) reports a series of 40 cases in which an attempt was made to give 600 mg. of lead in six to eight weeks, following the method of Blair Bell. This did not prove possible, however, and half the patients received only 350 mg. The combination of lead and *x* rays was found to be more effective against the neoplasm than either used alone. Of the 40 patients, only 8 are living; 4 still show extensive tumours, while the remaining 4 are wholly free from physical signs of the disease. No death could be attributed to the lead. The author believes that in a few cases arrest of the disease may be obtained by the combined administration of lead and *x* rays.

342. The Antiseptic Value of Rivanol Dextrose.

T. C. HILL (*Amer. Journ. Surg.*, January, 1929, p. 67) gives the results of his experiments with rivanol dextrose on rats and rabbits, and finds that there has been marked success in infections of the urinary tract, as, apart from its sterilizing properties, it is able to build up an antiseptic wall between the focus and the general circulation by means of circular infiltrations around the progressing infection. Rivanol,

which, like acriflavine, is a member of the acridine group, is less toxic than its congener, and the soluble hydrochlorate was first used; later its irritating qualities were further reduced by combining two parts of dextrose with one of rivanol lactate. The preparation has shown marked efficiency in the treatment of acute gonorrheal urethritis, thanks to its accompanying analgesic action and relief of symptoms. Definite signs of improvement appeared in cases of pyelitis after irrigation with a 1 in 2,000 dilution of rivanol dextrose. It was also used for irrigation of the urethra and bladder, and three cases of tuberculous cystitis were effectively treated in a similar way. Rivanol dextrose has a great analgesic, antiphlogistic, and secretion-diminishing action in severe forms of cystitis. The anodyne action was especially remarkable in these cases, the inflammatory catarrhal signs improved rapidly, the sclerotic changes diminished, and the bladder capacity increased. It has also been used in the treatment of prostatic infection with some success. The lack of toxicity of this agent permits the employment of large amounts of the diluted solution, and its transparency and non-staining properties enhance its utility.

343. Bismuth in Lupus Erythematosus.

J. NICOLAS, J. LACASSAGNE, and J. ROUSSET (*Paris Méd.*, January 19th, 1929, p. 62), impressed by the good results obtained in the treatment of nodular lupus by bismuth, have been systematically treating all their patients with lupus erythematosus by means of this drug, and publish in detail a list of seventeen who received injections of bismuth salts. Analysis of the results of treatment shows that all the patients received great benefit and many were apparently cured. Relapses followed in a small minority of the cases, but a further course of treatment rapidly cleared up the lesions. The results were nearly always complete at the end of the first series of injections, the symptoms and objective signs abating definitely during the first few doses. The skin usually became normal, except in a few cases where a little redness persisted. A series of twelve intramuscular doses of bismuth hydroxide (1.80 grams in all) was usually given, but one patient received fifteen doses. In addition to the favourable local results there was improvement in the general condition. The authors briefly discuss the etiology of the disease and favour its tuberculous origin. They claim that bismuth should be given in preference to other drugs in the localized and extensive or painful forms, or again in centrifugal erythema, on account of the constancy of its action, of the immediate alleviation without reaction, and of the good terminal results.

Laryngology and Otology.

344. The Visual Fields in Atrophic Rhinitis with Ozaena.

T. MAGNOTTI (*Arch. Ital. di Otol.*, November, 1928, p. 629) has examined a series of thirty cases suffering from atrophic rhinitis with ozaena. He investigated the visual fields with the perimeter for various colours and the fundi by means of the ophthalmoscope. In the majority of these cases the vision was normal for ordinary purposes, and where it was abnormal the error was usually one of refraction. Vision was most acute among the colours for yellow, and next for red: it was reduced most for blue and green. Examination of the visual fields showed that the field was reduced most for white, and that the field for green was often as large as that for red and even for white. The fields were reduced only on the temporal side for white in eight cases, for red in fifteen, and for green in four. The fields were reduced concentrically for white in twenty-two cases, for red in fifteen, and for green in six. The fundus appeared coppery red, with the optic disc more red than usual and its margins not so well defined. It is possible that the brownish tinge in the fundus is due to an affection of the sympathetic nerve supply to the pigment cells of the retina and choroid, and that this is due to an irritation by the nasal disease of branches of the trigeminal nerve. It may be comparable with the discoloration of the skin in cases of Addison's disease.

345. Malignant Tumours of the Nasopharynx.

F. K. HANSEL (*Arch. of Oto-Laryngol.*, January, 1929, p. 12) reviews one hundred and forty reported cases of malignant tumours of the post-nasal space, twelve of which have occurred in his own practice. The tumour is almost always situated in the fossa of Rosenmüller, and tends to invade the Eustachian tube and body of the sphenoid. The mass of the tumour varies, but it may fill the post-nasal space. When the tumour extends outwards into the spheno-maxillary and pterygo-palatine spaces, important structures, particularly the nerves, are involved; of these the sixth is the most commonly affected owing to its low position in the sphenoid fissure. Later the second, third, fourth, and fifth are affected in the same neighbourhood, the fifth being attacked early. The seventh is not involved until the growth has extended back to the stylomastoid foramen. The last four cranial nerves are usually affected together as they pass out of the jugular foramen, but the eighth nerve escapes. The nasal symptoms are obstruction, discharge, foul smell, and haemorrhage, with some bulging of the palate. Deafness and tinnitus may occur when the Eustachian tube is affected. Extranasal symptoms are most marked when the nasal symptoms are absent or slightly marked. The extranasal symptoms are those caused by irritation or destruction of the cranial nerves. The tumours are epitheliomas, sarcomas, or lymphosarcomas. Treatment consists of irradiation, but the results are unsatisfactory.

346. Otogenic Meningitis.

R. MOE (*Norsk Mag. f. Laegevid.*, November, 1928, p. 1908) records his observations on 79 cases of otogenic meningitis which occurred in the oto-rhino-laryngological department of the National Hospital at Oslo during the period 1914 to 1927. In striking contrast with other statistics, most of which give an incidence of 50 per cent., the number of cases of meningitis complicated by labyrinthitis was very small—namely, only 9 (11.4 per cent.). Another peculiarity was the relatively bad prognosis in the female sex, since while 17 patients recovered there were 15 out of 58 men and only 2 out of 21 women. The date of onset of meningitis in cases of acute otitis was as follows: first week, 11 cases; second week, 1 case; third week, 9 cases; fourth week, 14 cases. Treatment was on the usual lines, operations on the labyrinth and incision of the dura mater being very rarely employed. Operations on the labyrinth were usually performed by Ruttin's method as soon as signs of meningeal irritation appeared after labyrinthine symptoms had subsided. The dura was only incised when a cerebral abscess or other subdural accumulation of pus had been found by puncture, the size of the incision being always very small. The only drug used was urotropine, which was given intravenously in a large single dose. No bad effects of a permanent nature on the urinary system were observed from its use. No benefit was ever seen from the use of antistreptococcal serum.

Obstetrics and Gynaecology.

347. Cardiac Disease in Pregnancy.

B. E. HAMILTON and F. S. KELLOGG (*Journ. Amer. Med. Assoc.*, December 22nd, 1928, p. 1942) are convinced that the problem of heart disease complicating pregnancy is not generally understood, and summarize their conclusions which were based on seven years' intensive study of heart diseases in pregnant women at the Boston Lying-in Clinic and in private cases. They classify these cases in three groups. In the first are placed patients with severely injured or disordered hearts. These require very special care, and it is highly desirable to differentiate those who will tolerate pregnancy from those who will not. Patients who have or have had heart failure or a less common complication, such as auricular fibrillation or hypertension, do not tolerate pregnancy well, and are grouped as Class Ia; in these abortion and sterilization, when practicable, are justifiable. Mitral stenosis and acute rheumatic fever (which is rare in pregnant women) also contraindicate pregnancy for cardiac reasons. The second class contains all "possible cardiacs" and those patients believed to have rheumatic or congenital heart disease or other cardiac condition, but who do not show clear signs of injury. In the third class are placed those definitely without heart disease, the majority suffering from cardiac neurosis or neuro-circulatory asthenia. In the second and third classes the heart condition can safely be disregarded so far as pregnancy is concerned. The satisfactory medical control of patients in the first class consists in the observance of three fundamental rules: accurate diagnosis, early recognition, and persistent pre-natal control. Most of the deaths of cardiac patients in pregnancy are due to ordinary congestive heart failure, the causes of which usually are over-exertion and infections, such as colds, influenza, or tonsillitis. If failure occurs early in pregnancy, the latter should be interrupted, and, even if it supervenes in the late months, the continuance of pregnancy is dangerous. Pregnancy should not be allowed to continue if the patient has or has had failure or a dangerous complication. If heart failure occurs despite all precautions, it should be recognized early, relieved, and the patient delivered before it reappears. Caesarean section is the easiest method of delivering a patient with cardiac disease, and skilled anaesthesia is essential. For the latter Kellogg's choice is a single dose of morphine-scopolamine, followed by very careful administration of ether dropped on gauze, or by ether-oxygen vapour.

348. Umbilical Endometrioma.

H. BALTZER (*Zentralbl. f. Gynäk.*, January 12th, 1929, p. 99) remarks that endometrioid tumours of the navel, besides furnishing the most conspicuous difficulties with regard to the various theories which have been advanced concerning the genesis of heterotopic adenomyosis, are not devoid of practical importance in that they may require more extensive treatment than might at first sight appear. He quotes a case recently reported by Vogt in which an endometrioid tumour of the intestine led to ileus, and records a personal case in which laparotomy after removal of an umbilical "endometrioma" showed the presence in the sigmoid colon of an "endometrioma" the size of a hazel-nut, from which radiated cicatricial bands which were judged likely to lead to intestinal obstruction. A woman, aged 40, who had had one child thirteen years previously, had noticed for two months a tumour near the navel which was painful during menstruation, had attained the size of a pear, and exhibited beneath the skin a bluish coloration. A pre-operative diagnosis of umbilical endometrioid tumour was made. The growth was removed extraperitoneally, and subsequent coeliotomy showed, in addition to the tumour of the sigmoid (which was extirpated and found to have microscopical appearances characteristic of "endometrioma"), two small nodules on the posterior abdominal peritoneum and an unruptured corpus luteum cyst of the left ovary.

349. Uterine Prolapse.

J. C. MASSON (*Minnesota Med.*, February, 1929, p. 67), discussing the surgical treatment of uterine prolapse, condemns any routine type of operation as being too radical for some cases and insufficient in others. He classifies cases for operative treatment under four main headings: (1) those in which the function of child-bearing is to be preserved; (2) those in which the production of sterility is contra-indicated; (3) those near or past the menopause; and (4) those in which partial or complete obliteration of the vagina is the best treatment. Much of the necessity for operations in later life could be avoided by earlier and adequate treatment of subinvolution, pelvic infections, and lacerations of the cervix and perineum. Most women date their symptoms from their first confinement. Since the condition is a hernia, the type of operation requires careful consideration according to the extent of the trouble, the size of the associated cystocele, the age and marital state of the patient, and the relative danger of an abdominal or perineal operation. Perineorrhaphy is always essential, while in difficult and recurrent cases obliteration of the vagina may be advisable.

Pathology.

350. Cellular Permeability.

I. H. PAGE (*Amer. Journ. Med. Sci.*, February, 1929, p. 273) discusses two cases of ipsilateral oedema and contralateral jaundice associated with hemiplegia and cardiac decompensation as having a bearing on the mechanism of permeability. At present there is no definite proof of the direct control of permeability by the nervous system, though many experiments have suggested that such a control exists. Various secretions, such as the saliva, seem to be liberated as the result of changes caused by a nervous impulse. Hemiplegia produces vasomotor paralysis or instability, as was evidenced by the trophic changes in the limbs on the right side and the ipsilateral cyanosis noted in one of the cases reported by Page. A paralytic dilatation of the capillaries, resulting from lack of tonic influence of the vasomotor system, may cause active transudation of fluid. According to Landis, this is not due to the dilatation *per se*, but to a change in cell permeability. Local anoxaemia, as a result of deficient oxygenation of the pulmonary blood and increased oxygen consumption due to stagnation of the blood in the capillaries, may be a causative factor of these changes. Meakins has pointed out that two varieties of jaundice occur in circulatory failure: the haemolytic type, in which there is either an excess of the precursors of bile pigments produced in the spleen, or an inability of the liver to transform these into bile pigments; and the obstructive type, where, although the bile pigments are formed and secreted into the bile capillaries, they are prevented from passing into the larger ducts. It is difficult to understand why bile pigments do not enter oedematous tissues. It has been proved that the size of the molecule need not necessarily influence the selective penetration of a substance; therefore size is not the sole reason for the non-penetration. Page suggests that the turgor of the cells, due to the oedema, may in some way hinder the entrance of the pigment, but so many factors require further study that an explanation can at present be only speculative.

351. The Bacteriophage in River Water.

D. BUJANOWSKI (*Centralbl. f. Bakt.*, January 11th, 1929, p. 129) has made some observations on the presence of a bacteriophage in the water of the River Don. He found that if a twenty-four-hour culture of *B. typhosus*, *B. paratyphosus* A or B, or *B. coli* was added to 100 c.cm. of river water so that there were about 5,000 organisms per cubic centimetre, and the water was kept at room temperature in the dark, the bacilli died out in two or three weeks. If, however, the water was sterilized in the autoclave before being inoculated, the organisms remained viable for at least six months. The germicidal action of raw river water on pathogenic bacteria has been frequently observed, and has been ascribed by different workers to the antagonistic effect of the natural water bacteria, to the actinic rays of the sun, or to some other cause. To exclude the first possibility the author filtered the water through a Chamberland candle, and then inoculated it in the usual way. The results were the same as with the crude river water—that is to say, the organisms died out in two to three weeks in the filtered water, whereas in the autoclaved water they survived for months, and actually underwent multiplication. When *B. typhosus* and *B. paratyphosus* A were inoculated into filtered river water to which 1 per cent. of peptone had been added, no visible turbidity developed; the filtrate of these cultures was found to have a lytic effect on broth cultures of these organisms. Plating experiments showed that the lytic effect was due to the presence of a bacteriophage, capable of producing on solid media typical sterile plaques and "bitten" colonies. The author concludes that the water of the Don has a bactericidal effect on the intestinal bacteria; that this effect is due to a bacteriophage; and that this is responsible to some extent for the self-cleansing of the river.

352. Immunization against Diphtheria by Anatoxin.

P. J. MOLONEY, D. T. FRASER, and MLLE C. J. FRASER (*Ann. Inst. Pasteur*, January, 1929, p. 124) find that the intradermal injection of anatoxin, diluted 1 in 20, gives rise in a certain proportion of subjects to a marked local reaction. This reaction, which is due to protein hypersensitiveness, is rarely observed in children under the age of 6; it was positive in 7 per cent. of subjects between 5 and 9, in 29 per cent. between 10 and 19, and in 37 per cent. between 20 and 35 years of age. Using anatoxin in place of heated toxin as a control in the performance of the Schick test, the authors observed the usual four types of reaction. Subjects reacting positively to toxin and negatively to anatoxin are susceptible to diphtheria; those reacting negatively to toxin, and either positively or negatively to anatoxin, are immune to diphtheria; with subjects reacting positively both to toxin and anatoxin it is necessary to examine the antitoxin content of the blood. This was done in 26 cases, and in 22 of them more than one fiftieth of a unit of antitoxin was found, indicating that only 4 of these double positive reactors were susceptible to diphtheria. The authors have used injections of anatoxin for producing active immunity; three doses are recommended, of 0.5 c.cm., 0.5 c.cm., and 1.0 c.cm., at intervals of three weeks. This method appears to succeed in converting Schick positive into a Schick negative reaction in about 80 to 100 per cent. of patients. Persons who react to the intradermal injection of anatoxin must be given smaller doses, otherwise a severe local and constitutional reaction may occur.

353. Toxicity of Manganese in Pulmonary Tuberculosis.

J. V. LAMBEA (*La Med. Ibera*, February 2nd, 1929, p. 13) records the results of his investigations with manganese sulphate in experimental tuberculosis in guinea-pigs and rabbits, as well as in human tuberculosis. He found that the toxic effects of this drug were similar to those of other metals with which he had experimented, such as copper, cerium and cobalt salts, and the double chloride of gold and sodium. Manganese sulphate produced lesions of an irritative and degenerative character in the kidneys, haemorrhage in the lungs, and degeneration of the liver. Tuberculous rabbits were much more sensitive to injections of manganese sulphate than healthy animals, as Lambea had found in his experiments with other metals. Guinea-pigs which had been inoculated with tuberculous virus became worse after injections of manganese. Lastly, tuberculous patients, after intravenous injections of manganese in doses of 5 to 10 mg. complained of a feeling of tightness in the epigastrium, followed by difficulty in breathing or headache and slight and transient pyrexia. These symptoms were doubtless due to the exudative and haemorrhagic changes produced by the metal and the discharge into the circulation of the toxic products. Large doses gave rise to more violent symptoms, including diarrhoea, vomiting, and a sense of anguish. There was a frequent but not constant lymphocytosis. Large doses were liable to produce anisocytosis, poikilocytosis, and polychromatophilia.

de KUYPER'S
HOLLANDS

Distilled from genuine malt liquor with the Juniper berry added. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from irritating properties.

Oleum Juniperi is official in the British Pharmacopœia, and is described as carminative, anti-spasmodic, and a stimulating diuretic.

In this form, therefore, the oil of Juniper can be safely taken with regularity.

Distilled by the same family for 233 years.

FELAMINE

BRAND
SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:

CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

PROVED MORE EFFICIENT THAN NICKEL-PLATED INSTRUMENTS

NOT once, but many times, Doniger Krome-Plate Instruments have proved their superiority in practical tests carried out in some of the most important hospitals and clinics of America.

The reason for this superiority is not far to seek. Doniger Instruments are made from high carbon steel of fine quality. They are fashioned by master craftsmen and polished to the highest degree of smoothness. They are then nickel-plated, and finally given a heavy plating of pure chromium. This treatment makes Doniger Instruments—

(a) much harder and stronger;
(b) rust-resisting;
(c) last five times as long as nickel;
(d) retain their original brightness.

These advantages make the use of Doniger Instruments a very real economy, especially so in conjunction with the fact that Doniger Instruments cost only a fraction more than nickel-plated Instruments.

You are invited to apply to your usual Supply House for full particulars and prices.

Doniger Instruments are not supplied direct to the Profession.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

BOVRIL has unique BODY BUILDING POWERS

as shown by the physiological experiments of the late Sir William H. Thompson, Trinity College, Dublin.

Prescribed in numerous cases *of nervous and heart disorders, also rheumatic conditions, etc.*

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, an[illegible] to the Hospital from the farm, gardens, and orchards of Moulton is a feature of this branch, and patients are given every facility in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc

For terms and further particulars apply to the Medical Superintendent (Telephone: No 56 Northampton), who can be seen in London by appointment.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK ST., LONDON, W.1. Tel: Langham 1166.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S.ENGLAND. (Primary & Final.)
F.R.C.S.EDINBURGH.
CH.M.EDINBURGH.
M.C.CANTAB.
M.S.LONDON.

And all other Surgical Degrees and Diplomas.

The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions get through without difficulty after going through our courses.

The Surgical Tutors of the College all hold either the M.S.Lond. or F.R.C.S.England, or both, and are highly experienced teachers.

The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

VALUABLE BOOK

"How to Pass the F.R.C.S.," free on application to the Secretary.

THE
LONDON HOSPITAL MEDICAL COLLEGE.
(University of London.)

UNIVERSITY of CAMBRIDGE.

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY (D.M.R. & E.).

The Course of study for the Diploma, which is open only to duly qualified medical men and women, begins on October 1st, 1929, and occupies nine months. The examinations consist of three parts:

1. Physics, with examinations in January and April
2. Radiology and Electrology, with examinations in April and July.
3. The presentation of a thesis or exercise which is entirely the candidate's own work, and is intended to show that he has had practical experience of the subjects.

The first three months may be spent either in Cambridge, where the Physics is done in the Cavendish Laboratory and the Radiology and Electrology in a specially equipped Department of Radiology, or in London, where the Physics is done in the Laboratories of the Middlesex Hospital and King's College and the Radiology and Electrology is taught at the British Institute of Radiology. These Courses run concurrently in Cambridge and London.

The second three months must be spent in London, where courses of lectures are given at the British Institute of Radiology, and are combined with clinical instruction in the large teaching hospitals.

The third three months may be spent in recognized hospitals in London or elsewhere, the student acting as clinical assistant or in similar capacity.

Further information as to the Courses may be obtained from:

G. STEAD, M.A., Secretary for the Diploma and Lecturer in Physics as applied to Medical Radiology, Cavendish Laboratory Cambridge.

A. E. BARCLAY, O.B.E., M.A., M.D., Lecturer in Radiology, Department of Radiology, Medical School Cambridge.

The Director of the British Institute of Radiology, 32, Welbeck St. London, W.1.

March 27th, 1929

WEST AFRICAN MEDICAL STAFF

VACANCIES exist for MEDICAL OFFICERS and MEDICAL OFFICERS OF HEALTH in the BRITISH WEST AFRICAN COLONIES.

SALARIES.

Medical Officers receive salaries at the rate of £660 a year, rising by annual increments of £30 to £720 a year, and then on confirmation £720 a year, rising by annual increments of £40 to £960 a year, together with a seniority allowance (payable only in West Africa) at the rate of £72 a year. After three years' service on £960, the salary may be raised to the scale of £1,000 a year, rising by annual increments of £50 to £1,150 a year, together with a seniority allowance at the rate of £100 a year.

Medical Officers of Health receive salary on the above scale beginning at £800 a year, together with seniority allowance of £72 a year. They also draw staff pay at the rate of £150 a year, half of which is payable during leave.

QUARTERS.

Free furnished quarters are provided or an allowance in lieu.

OUTFIT ALLOWANCE.

An outfit allowance of £60 is granted on first appointment.

PASSAGES.

Free first-class passages are provided on first appointment, and when proceeding on or returning from leave.

PENSIONS.

All appointments are pensionable; a minimum service of seven years is required to qualify for a pension. An officer may retire on reaching the age of 50 and may be called upon to retire at the age of 55. Officers of the West African Medical Staff are permitted to retire if they wish with a gratuity of £1,000 or £1,250 after nine or twelve years' approved service respectively, but in that event they receive no pension.

TOURS OF SERVICE AND LEAVE.

A tour of service in West Africa lasts from twelve to eighteen months at the discretion of the Colonial Government, and is followed by leave at the rate of one week for each completed month of residential service. Leave begins on the date of arrival in England.

PROMOTION.

There are good prospects of promotion in the West African Medical Staff.

COURSE OF INSTRUCTION.

Selected candidates are required to attend courses of instruction in tropical medicine and hygiene at either the London School of Hygiene and Tropical Medicine or the Liverpool School of Tropical Medicine or the University of Edinburgh.

Further information regarding the conditions of service, pensions, etc., may be obtained from the Private Secretary (Appointments), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1, to whom applications should also be addressed.

ROYAL AIR FORCE

MEDICAL SERVICE

VACANCIES exist for MEDICAL OFFICERS in the ROYAL AIR FORCE

1. CONDITIONS OF APPOINTMENT

Candidates are selected after interview by a Selection Board.

SHORT SERVICE COMMISSIONS (for THREE YEARS extensible to FIVE) are granted initially.

PERMANENT COMMISSIONS are granted subsequently to suitable officers who are desirous of them. Approximately half the entrants obtain permanent commissions.

CANDIDATES must be of pure European descent, British subjects and the sons of British subjects.

They must be UNDER 28 YEARS OF AGE, and REGISTERED under the Medical Acts in force in the United Kingdom.

Resident hospital appointments held since qualification for twelve months under certain conditions qualify candidates for a year's ANTEDATE of Commission.

Candidates must engage to serve at home and abroad, and to fly as a passenger when required.

2. PAY, PROMOTION, ETC.

The following table shows the current rates of PAY per annum for the various ranks.

IN ADDITION to pay, officers receive quarters, rations and attendance, or are given cash ALLOWANCES in lieu as shown in the table.

MARRIED OFFICERS who have attained the age of 30 YEARS receive either Married Quarters or ALLOWANCES at the MARRIED RATES.

ALLOWANCES to meet the extra cost of living OVERSEAS are given.

Service.	Rank.	Pay.	Allowances.	
			Married.	Single.
On entry	Flying Officer	£411	—	£142
After 2 years on promotion to	Flight Lieut.	£447	£202	£160

Thakeham Union.

MEDICAL OFFICER AND PUBLIC VACCINATOR.

The Guardians invite applications from fully qualified medical practitioners for the appointment of Medical Officer and Public Vaccinator of the No. 1 District (9 parishes with an estimated population of 4,050).

The salary as Medical Officer will be at the rate of £112 per annum and the fees paid in respect of vaccinations are 8/- for each successful case, the appointment of Public Vaccinator being subject to one month's notice on either side.

The appointment (other than that of Public Vaccinator) will be subject to the Provisions of the Poor Law Officers Superannuation Act.

The person appointed will be required to attend at the houses of the outdoor patients, to supply all drugs, medicine, and appliances free (other than anæsthetics and cod-liver oil), and generally conform with the Orders of the Ministry of Health and the Guardians.

Applications, in candidates' own handwriting, stating age, qualifications, and present and previous occupations, and accompanied by copies of recent testimonials, should be sent so as to reach my office without delay.

Canvassing, either directly or indirectly, will be deemed a disqualification.

Storrington, Pulborough, Sussex. April 2nd, 1929.

PERCY AYLING, Clerk to the Guardians.

Nottinghamshire County COUNCIL.

APPOINTMENT OF SCHOOL DENTIST.

Applications are invited for the appointment of a whole-time School Dentist at a salary of £500 per annum, rising after two years' satisfactory service by increments of £25 to a maximum of £550. Travelling expenses will be paid in addition according to the scale approved by the County Council.

Candidates must be fully qualified and registered Dentists, and the person appointed will be required to perform such duties as may be from time to time prescribed by the County Education Committee, and to devote his whole time to the duties of the office. He will be a member of the staff and act under the control and direction of the County Medical Officer of Health, and required to reside in a part of the County to be approved by the Education Committee.

The appointment will be terminable by three months' notice on either side.

Application, on the prescribed form (which may be obtained on application to me), accompanied by copies of not more than three recent testimonials, should be forwarded to The County Medical Officer, Shire Hall, Nottingham, not later than April 10th.

Shire Hall, Nottingham. March 23rd, 1929.

K. TWEEDALE MEABY, Clerk of the County Council.

Stoke and Wolstanton Union.

SECOND ASSISTANT RESIDENT MEDICAL OFFICER (Male).

Applications are invited for the appointment of Second Assistant Resident Medical Officer (male) at the London Road Institution of this Union

Salary £200 per annum, with board and residence. The period of the appointment will be limited to one year in the first instance, subject to termination by one month's notice on either side.

The accommodation at the Institution is approximately 1,154 beds, including 600 hospital beds and 150 in Mental Wards. The Hospital is a recognized Training School for Nurses.

Applications, stating particulars of qualifications or degrees held, the date thereof, when taken, and experience since qualifying, together with copies of three testimonials of recent date, should be delivered to the undersigned not later than first post on Wednesday, April 10th.

Union Offices, Stoke-upon-Trent. April 2nd, 1929.

T. WOOD, Clerk to the Guardians.

Connaught Hospital for WALTHAMSTOW, WANSTEAD, AND LEYTON, Orford Road, Walthamstow, E.17. (100 Beds.)

RESIDENT HOUSE PHYSICIAN (male) required. Salary £100 per annum.

RESIDENT HOUSE SURGEON (male) required. Salary £100 per annum.

Each appointment to date from May 1st, and to be for a period of six months.

Applications, with three testimonials (or copies), should be sent to the Secretary to reach him not later than April 10th.

United Services Fund.

HEATHERWOOD HOSPITAL, ASCOT.

RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited from fully qualified medical practitioners (bachelor, not over 30) for the above post.

Candidates must have held some appointment in a General Hospital.

The present Hospital accommodation is 136 beds for the treatment of surgical tuberculosis and other forms of crippledom.

The appointment will be for a period of twelve months and may be extended at the end of that time.

Remuneration is at the rate of £300 per annum, together with residence, board, and laundry.

The officer appointed will be required to devote the whole of his time to the duties of the office, to give anæsthetics, etc., and generally to act under the supervision and direction of the M[illegible]

(1) age, (2) qualifications and appointments held, accompanied by three copies of recent testimonials, should be forwarded to the Secretary, Heatherwood Committee, United Services Fund, 29, Cromwell Road, South Kensington, London, S.W.7, before April 12th.

Further particulars can be supplied on application to the Medical Superintendent, Heatherwood Hospital, Ascot, Berks.

Poplar Board of Guardians.

APPOINTMENT OF TWO ASSISTANT MEDICAL OFFICERS.

The Guardians of the above-named Parish hereby give notice that they will, at their meeting to be held on April 24th next, proceed to the appointment of Two Assistant Medical Officers at the ST. ANDREW'S HOSPITAL, Devons Road, Bow, E.3, at a basic salary of £228 per annum, by two instalments to £254, thence by one instalment to £260, together with bonus in accordance with the Civil Service Award, producing at present a total commencing salary of £350, with board, lodging, and washing

The persons appointed will be required to carry out such duties as may be required of them by the Medical Superintendent of the Hospital, or the Guardians.

Special consideration will be given to candidates who hold qualifications and have had experience in up-to-date maternity work.

Form of application may be obtained from the Clerk to the Guardians, 45, Upper North St., Poplar, E.14, and must be returned, with copies of not more than three recent testimonials, not later than first post Monday, April 15th.

By Order,
45, Upper North St., Poplar, E.14.

G. BUTLER, Clerk to the Guardians.

Birmingham Public Health DEPARTMENT.

TUBERCULOSIS SECTION.

Applications are invited for the appointment of an ASSISTANT MEDICAL OFFICER from single male medical practitioners, not over 40 years of age. The duties include both Sanatorium and Dispensary work, and special experience in the treatment of Bone Tuberculosis is essential. Applicants should have been qualified for three years, and it would be a recommendation if a resident General Hospital appointment had been held.

The candidate appointed would be required to pass a medical examination, in connection with the Municipal Superannuation Scheme. The salary offered is at the rate of £450 per annum, together with board, residence, and laundry, estimated for superannuation purposes at £150.

Applications, accompanied by copies of three recent testimonials, stating age, qualifications, and experience, should be received not later than April 13th by the Chief Tuberculosis Medical Officer, 44a, Broad St., Birmingham.

Northampton Education COMMITTEE.

ASSISTANT SCHOOL DENTIST.

Applications are invited for the appointment of a fully qualified Dental Surgeon (man or woman) as Assistant School Dentist. Salary £450 per annum.

Further particulars and forms of application may be obtained from the undersigned, by whom applications should be received by not later than April 12th.

Education Office, 4, St. Giles' St., Northampton.

A. C. BOYDE, Director of Education.

Romford Union,

OLDCHURCH HOSPITAL.

RESIDENT SECOND ASSISTANT MEDICAL OFFICER.

The Guardians of the Romford Union invite applications for the appointment of a Second Assistant Resident Medical Officer (male) at their Oldchurch Hospital, Romford, which has a present accommodation of 550 beds.

Applicants must be single, and preference will be given to one who has held the position of House Surgeon or House Physician in a General Hospital.

The appointment is governed by the regulations laid down in the orders of the Ministry of Health.

The salary will be at the rate of £250 per annum, subject to deductions under the Poor Law Officers Superannuation Act, 1896, and furnished apartments, maid, rations, and laundry.

Forms of application may be obtained from the undersigned upon receipt of a stamped addressed foolscap envelope, and must be returned not later than Monday, April 15th.

By Order,
Union Offices, Romford. March 28th, 1929.

R. H. MASON, Clerk to the Guardians.

County Borough of Bootle.

ASSISTANT SCHOOL MEDICAL OFFICER and ASSISTANT MEDICAL OFFICER OF HEALTH (Woman).

Applications are invited for the appointment of Assistant School Medical Officer and Assistant Medical Officer of Health (woman) at a salary of £600 per annum, rising by £30 annually to a maximum of £750 per annum. Particulars of the duties (which include School Medical Inspection and the conduct of Maternity and Child Welfare Clinics) and forms of application may be obtained from the Medical Officer of Health, Town Hall, Bootle.

Applications, accompanied by copies only of not more than three testimonials, endorsed "Assistant Medical Officer," must be returned to me on or before April 20th.

Canvassing, either directly or indirectly, will disqualify candidates.

Town Hall, Bootle. April 2nd, 1929.

J. SPENCER TUMILTY, Town Clerk.

County of Lanark.

DISTRICT OF THE MIDDLE WARD.

COUNTY ORTHOPÆDIC HOSPITAL, STONEHOUSE. (100 Beds.)

Applications are invited for the post of RESIDENT MEDICAL OFFICER (male) at the above Institution. Salary £600, rising to £[illegible] by £50 biennial increments. Free board and lodging will be provided. The appointment will be subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Candidates must have special experience of the treatment of *non-pulmonary* tuberculosis and of modern orthopædic methods. Experience in operative surgery is also essential.

Applications, stating age, experience, etc., accompanied by copies of not more than three recent testimonials, must be lodged with the Subscriber not later than April 22nd, endorsed "Medical Officer." Canvassing will be a disqualification.

Hamilton. March 28th, 1929.

March 29th, 1929.

EVA E. HARDWICK, Secretary.

Sheffield Union Hospital.

RESIDENT ASSISTANT MEDICAL OFFICER.

The Guardians of the Poor of the Sheffield Union invite applications for the appointment of a Resident Assistant Medical Officer at the Union Hospital, Firvale, Sheffield. The Hospital is a large separate Institution containing 840 beds, and is equipped in accordance with modern requirements, and facilities are provided for Pathological and Bacteriological work.

The staff at present consists of a Resident Medical Superintendent, a Resident Deputy Medical Superintendent, and five Resident Assistant Medical Officers, a Visiting Physician, a Visiting Surgeon, and a Visiting Radiologist. The Assistant Officer to be appointed will be required to take duty in such parts of the Hospital or at other Institutions under the control of the Board as may be directed.

Applicants must be duly registered under the Medical Acts, and qualified by law to practise Medicine and Surgery in England and Wales.

The appointment will be limited to two years, the salary being at the rate of £250 for the first year, and £300 for the second year, together with residence, rations, and other usual allowances, the salary being subject to the statutory deductions required by the Poor Law Officers Superannuation Act, 1896.

Letters of application, stating age, qualifications, and experience, together with copies of testimonials of recent date as to professional ability and personal character, to be sent to me without delay.

By Order,
LAWRENCE RICHMOND,
Clerk to the Guardians.

Union Offices, West Bar, Sheffield.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3543 (5 Lines)

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non-panel general and surgical Practice can *be acquired by a suitable gentleman possessing the* F.R.C.S. degree. Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation, at present held on lease with *option* to purchase. Premium 2 years' purchase.
2. SOUTH-WESTERN COUNTY.—LARGE SEAPORT TOWN.—Old-established mixed-class PRACTICE averaging over £3,000 p.a., including panel of 2,100. Visits 3/6 to 10/6; midwifery (discouraged of late) 3 gns. upwards, about 30 cases yearly. Expenses light (Assistant not necessary). House contains professional accommodation, 3 sitting, 6 bedrooms, bathroom, etc. Large garden, garage. Vendor's freehold price £2,800, of which £1,200 *can remain on mortgage, or might* be rented at £96 p.a. Premium 1½ years' purchase, £3,000 down and balance by arrangement.
3. BUCKINGHAMSHIRE.—Country PRACTICE, situated in delightful district within 50 miles of London.—*Old-established mixed general* Practice, producing a steady average income of £2,000 p.a. Panel brings in about £700 p.a. Moderate expenses. Fees from 2/6 to 21/-. Under 30 midwifery cases yearly. *Exceptionally nice and* well-situated house, with 2 reception, 6 bedrooms, etc.; separate entrance to professional rooms. Large garden, with tennis court. *Price for freehold £1,500. Hunting, golf, and other sport.* Premium £3,000.
4. HOME COUNTY.—Within 40 miles of London.—In small Village (with large surrounding population) in pleasant district, old-established *mixed and increasing* PRACTICE, worth last year *nearly £3,600*, including Union and Vaccination over £100, and panel producing over £1,150. Railway station in place. House contains surgery and waiting rooms (separate entrance), 2 reception, 4 bedrooms, bathroom, etc., large garden. Gas, electric light available. Price for freehold £2,500, part mortgage. Premium 1½ years' purchase. Good society, sport, etc. Vendor keeps an Assistant, but investment would admirably admit of taking a partner later on, as houses available.
5. DEATH VACANCY.—NORTHANTS.—Country district, near large town.—Mixed-class PRACTICE, producing about £1,200 p.a., including panel of 300. Fees 3/6 to 10/6, with medicine extra. *Midwifery 2 to 5 guineas, about 20 cases yearly. Excellent* well-built house, with 3 reception, 10 bedrooms, etc. Garden, garage. Price for freehold £2,500, £1,500 of which on mortgage. Hunting, *shooting*, fishing, etc. Schools within reach. *Premium one year's* purchase, or near offer.
6. KENT.—COAST TOWN.—Small, but increasing middle and working-class PRACTICE, producing for last 12 months nearly £600. Panel of 560. *Visits 3/6 upwards. Not much midwifery at from £3 3s.* Double-fronted eight-roomed house, with three-quarters of an acre of garden. Price for freehold £1,400. Premium £900.
7. *DEATH VACANCY—WEST MIDLANDS, CATHEDRAL CITY.—Old-*established good mixed Practice, producing for last 12 months about £900, including panel of over 1,000. Fees 3/6 to 10/6. Midwifery from 3 gns. Good house situated in best part of town, with 2 reception, 4 bedrooms, etc. Garden. Available on rent or by purchase; or if single, purchaser could board with widow. Sport of all kinds, and good schools. Offers invited.
8. LONDON, WEST END.—PARTNERSHIP.—A one-fourth or one-third share is for disposal in an old-established good-class non-panel, non-dispensing Practice. Net income of share £1,120. Fees one guinea upwards. Very little midwifery from 31 guineas. *Suitable flat* available for bachelor, or if married purchaser could choose his own place of residence. Premium for one-fourth share £2,250.
9. PARTNERSHIP.—SOUTH COAST.—In a popular and favourite watering-place, the third share (to commence) of an *old-established* mixed-class Practice, *offering great* scope for increase, is for disposal. Cash receipts nearly £1,900 p.a., including panel (increasing) of over 1,150. Visits 3/6 upwards. About 30 cases of midwifery. Eight-roomed house, with garden. Price for freehold £1,450, of which at least £1,000 can be obtained on mortgage. Premium 2 years' purchase.
10. SOUTH OF ENGLAND.—*In a pleasant town (pop. 11,000) within* 5 miles of favourite watering-place, old-established mixed-class and increasing PRACTICE worth nearly £1,300 last financial year, including transferable appts. and panel of 880. Excellent family *residence, standing in its own grounds (tennis court, flower garden,* etc.), with ample accommodation. Held at present on lease (2½ years *to run) at £90 p.a., and can eventually be bought for £1,700 or less.* Premium £2,040, to include drugs, fittings, some furniture, etc.
11. PARTNERSHIP.—SOUTH OF ENGLAND.—The two-fifths share (producing an income of at least £1,300 p.a.) can be acquired by a suitable gentleman in an old-established connection situated in an attractive town near the sea. Appts. and panel held. Visits 5/- upwards, medicine extra. Very little midwifery. Nice house available, held on short lease, but can be purchased. *Excellent educational facilities, and sport of all kinds. Premium 2 years' purchase.*
12. SOUTH-WEST OF ENGLAND.—PARTNERSHIP.—A one half share in a very old-established Practice situated in an attractive small town, amidst beautiful surroundings, and within easy reach of the coast. *Gross cash receipts for the past year over £2,900.* Panel of 1,218, which, together with appts., brings in about £900 p.a. Moderate expenses. Visits 2/6, plus mileage and medicine 2/6 and 3/6 extra. *Very suitable house, with 3 reception, 4 bedrooms, and usual* offices. Garden. Price for freehold £750, of which £350 on mortgage. Premium 2 years' purchase.
13. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to 10/6. Midwifery 2 to 7 *gns. Choice of houses. Sport of all kinds* and schools. Premium 2 years' purchase, part by arrangement if necessary. *Preliminary* outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
14. CORNISH RIVIERA.—In a small but rapidly growing town (pop. 5,000—6,000) on the Coast, an old-estab. PRACTICE producing last year over £1,000, including appts. and panel of 550 to 600. Opposition weak. *Delightful residence, standing in own grounds of 1¼ acres* (croquet and tennis lawns, etc.) and eminently suitable for Resident *Patients*, which Vendor has been in the habit of taking. Contains professional rooms, 4 reception, 9 *bedrooms*, 2 *bathrooms*, etc. Water and electric light. Garage. Price for freehold £4,000. Prem. £1,500.
15. LONDON, NORTH.—PARTNERSHIP.—A one-third share, to commence with, in a very old-established *mixed general* Practice. Income approximately £3,400, including appts. and panel of over 3,000. Surgery fees 2/- upwards, visits 3/- upwards. If unmarried, ingoing *Partner could reside with senior*; otherwise, suitable house available. Premium 2 years' purchase, half by arrangement.
16. LONDON, SOUTH-WEST.—Within three miles of Charing Cross.—PARTNERSHIP.—*A half share, with succession* to the whole in about two years, in a very old-established non-panel Practice, held by Vendor 26 years. *Steady average income of £2,300. Surgery fees* 2/6 and 3/6, visits mainly 5/- and 7/6. *Very little midwifery.* Good house, in main road, with garden. Held *on lease, with nearly* 15 years to run, at a rental of only £55 p.a. *Premium 2 years'* purchase. *Very good scope for increase.*
17. LANCS.—LARGE TOWN, within easy reach of Manchester and Liverpool.—Old-established PRACTICE. Average income for past 12 *months £1,500, including panel of nearly 1,500.* Fees 2/6 to 10/6. Good house, with nice garden. Can be rented on lease at £65 p.a. Premium only 1½ years' purchase for prompt sale.
18. KENT.—*COUNTRY PRACTICE*, within six miles of the Coast.—Old-established mixed general Practice. Income for past twelve months £1,672, including appts. about £60, and panel of over 700. Fees 3/6 to 21/-. Not much midwifery 2 to 7 gns. Good house, with 2 reception, 5 *bedrooms, etc. Large garden* and orchard. Garage for 2 cars. Price for freehold £1,350. Sport of all kinds, and a hack within reach. Premium £2,250.
19. PARTNERSHIP.—SOUTH COAST.—In a fashionable watering-place the two-thirds share is for disposal in a mixed *Homœopathic* and *Allopathic (roughly half and half) good-class non-dispensing*, non-panel conection, in which there is a certain amount of surgery, and ingoing partner *should* be an operating surgeon. Receipts average over £3,600 p.a. Fees up to 10/6. Very little midwifery. *Large and suitable maisonette* available, with ample accommodation, in excellent position. Garage. Rent, on lease, £250 p.a. Premium for share
20. PARTNERSHIP.— of Charing Cross— half share of an working-class Practice averaging about £2,100 p.a., including panel of 1,300. Visits 2/6 to 10/6. House contains, in addition to professional accommodation, 2 reception, 2 *bedrooms*, *bathroom*, kitchen, etc. Small garden. Nominal rental, on lease about £60 p.a. Premium 2 years' purchase.
21. KENT.—Old-established Country Practice, situated in favourite locality within 5 miles of the coast. Income for past 12 months £1,030. Surgery fees 3/6 *upwards, visits 5/-* to 21/-. Poor Law appt. and panel of about 380. Attractive commodious house, with separate professional rooms. *Small garden.* Price £1,800. *Premium £1,500.*
22. LONDON, NORTH.—Old-established centrally situated mixed PRACTICE. Income for the immediate past year £3,500, including panel list of 2,200 and appointments about £125. Fees, advice and *medicine 2/6 to 5/-.* Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Price £6,000, part by arrangement. Long introduction.
23. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — *In a large Hospital Town, within 80 miles of London*, a well established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample *professional* accommodation, viz., 4 rooms, dressing room, bathroom, etc. Premium £1,500 for plant (which has been *valued*) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

$C_8 H_{10} N_4 O_2 + H_2 O$

THE injurious action of caffein, to which the ailing, reconvalescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE**, we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance

HORMOTONE
BRAND

in disorders of the

CATAMENIA

and the

MENOPAUSE

Hormotone supplies the physiological stimulus to the endocrine glands, whose functional activity determines the normal catamenial flow.

When these internal secretions begin to fail at the period of the menopause, Hormotone acts both by substitution and homostimulation.

Dose: One or two tablets three times daily.

TISSUE-RESISTANCE & DISEASE

ALTHOUGH it may be argued that many of the crimes charged to focal infection and auto-sepsis have not been satisfactorily brought home to these causes, it can hardly be denied that parasitic organisms thrive in areas of lowered tissue-resistance, or that the course of every disease is favourably influenced by the cleaning-up of all possible sources of *blood-contamination*.

A wholesome activity of the eliminatory functions is helpful in nearly every illness; and it is as one of the most pleasant and effective—as well as the most harmless—of painless eliminants that Eno's "Fruit Salt" has, for sixty years, won increasing respect from the medical profession and from discriminating laymen alike.

Eno's "Fruit Salt" has the merit of stimulating peristalsis purely by increasing the water content of the bowel, thus effectively removing waste and harmful products by the agent normally employed by Nature. "Fruit Salt" is moreover exceptional among saline aperients for its physical texture, its prompt and uniform solubility, and for the fact that it contains no sugar, flavouring agents, or sulphates of magnesia or soda.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the *latest addition* to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "The Doctor's Emergency Reminder" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series

The Issue of the BRITISH MEDICAL JOURNAL is this week 39,000 copies.

JUST ISSUED NEW (4th) EDITION

GARRISON'S HISTORY OF MEDICINE

Dr. Garrison has just revised his book. In the New (4th) Edition he reviews all the important advances in our knowledge. Many new sketches of men, places, and events are given. There is a new chapter on medicine in prehistoric times. He reviews recent medicine in Soviet Russia, Italy, Spain, and the Latin-American countries.

Every fact, every change in our knowledge, every important step in medical history has been examined, weighed, and, if noteworthy, included in the New (4th) Edition. The valuable chronology of public hygiene and medicine has been greatly increased. So numerous and widely distributed were these additions that it was necessary to reset the entire book.

The BRITISH MEDICAL JOURNAL says Garrison's is "the most readable, and in some respects the most valuable, of medical histories. The record of progress is enlivened throughout by touches of human interest. The author is never dull. . . . We congratulate him on having produced a fascinating volume, which, while full of solid learning, can, unlike most histories of medicine, be read from end to end without a yawn."

By FIELDING H. GARRISON, M.D., Lieutenant-Colonel Medical Corps, U.S. Army, Surgeon-General's Office, Washington, D.C. Octavo of 996 pages, with numerous portraits and other pictures. Cloth, 55s. net.

Labat's Regional Anesthesia

NEW (SECOND) EDITION

Dr. Labat has subjected his work to a very thorough revision, some chapters having been entirely rewritten. In addition 68 new illustrations have been added. New advances, new instruments, new technique are all given here clearly and definitely.

Octavo of 567 pages, with 367 illustrations. By GASTON LABAT, M.D., Clinical Professor of Surgery, New York University and Bellevue Hospital Medical College. Cloth, 35s. net.

Crile's Problems in Surgery

NEW

This new book is a collection of informative post-graduate lectures delivered at Washington University by Dr. George W. Crile, of Cleveland. They are published in book form in response to a persistent demand by those who heard them.

Octavo of 171 pages, with 49 illustrations. By Dr. GEORGE W. CRILE, M.D., Cleveland. Cloth, 18s. net.

Lusk's Science of Nutrition

NEW (FOURTH) EDITION

In the preparation of the first edition of this book, more than twenty years ago, the endeavour was made to admit to the introductory chapter only such material as appeared to be susceptible of scientific proof, and to make it the key to the rest of the book. In this, the fourth edition, that chapter remains virtually unchanged. The rest of the book shows many important additions to the facts of metabolism and revisions of its theories.

Octavo of 844 pages, illustrated. By GRAHAM LUSK, Ph.D., Sc.D., LL.D., F.R.S.(Edin.), Professor of Physiology at the Cornell University Medical College. Cloth, 32s. 6d. net

McGuigan's Therapeutics and Pharmacology

NEW

Dr. McGuigan wrote with a definite objective—viz., to give a clear statement of the important facts of pharmacology and therapeutics, to show the basis for these facts, and to make clear their application. Theory is wedded to practice.

By HUGH ALISTER MCGUIGAN, Ph.D., M.D., Professor of Pharmacology and Therapeutics, University of Illinois College of Medicine. Cloth, 22s. net.

Mayo Clinic Monographs—Thrombo-Angiitis Obliterans

NEW

Clinical, Physiological, and Pathological Studies based on the observation of more than three hundred cases of thrombo-angiitis obliterans in the Mayo Clinic in the years 1922 to 1927.

By GEORGE E. BROWN and EDGAR V. ALLEN, Division of Medicine, Mayo Clinic, collaborating in Pathology with HOWARD B. MAHORNER, Fellow in Surgery, The Mayo Foundation. 12mo. of 219 pages, illustrated. Cloth 14s net.

Mayo Foundation Lectures—Plant Pathology & Physiology in Relation to Man

NEW

Presents in an authoritative manner many important problems of interest not only to plant pathologists, but to biologists, chemists, physiologists, pathologists, and physicians.

A Series of Lectures given at the Mayo Foundation and the Universities of Minnesota, Iowa, Wisconsin, The Des Moines Academy of Medicine, and Iowa State College. 1926—1927. 12mo of 207 pages, illustrated. Cloth, 12s. net.

W. B. SAUNDERS COMPANY Ltd. 9, Henrietta Street, LONDON, W.C.2

METHODS AND USES OF
HYPNOSIS AND SELF-HYPNOSIS.
By Bernard Hollander, M.D. 6s.

Dr. Hollander's new book is the result of thirty years' experience of experimental hypnosis and hypnotic treatment, and contains directions how to apply hypnotism for the treatment of functional nervous and mental disorders and moral failings, as well as detailed evidence of phenomena throwing light on the mysteries of thought-transference, clairvoyance, etc.

GEO. ALLEN & UNWIN, Museum Street, London, W.C.1.

1904-1928

Lectures on Conditioned Reflexes

By IVAN P. PAVLOV

This book concerns Prof. Pavlov's investigations of the cerebral hemispheres by the strictly objective method of conditioned reflexes.

It is a collection of articles, reports, lectures, and addresses which have appeared during the last 25 years, and represents the historical advance of Prof. Pavlov's researches.

EATAN
Pronounced E-TAN

NEURO TONIC
NUTRITIVE
DIGESTIVE
RECUPERATIVE

A great advance on Meat Juices, Jellies, Essences, etc., particularly in extreme Weakness, Gastritis, Fever, Debility, after Operations, Tuberculosis, etc. Very palatable. Non-Irritant.
Dr. Haff, after long experience in the transplantation of glands in deficiency diseases, conceived and produced the hydrolysates contained in Eatan for the positive regeneration of the body tissues, when the natural processes of metabolism fail to function normally.
A host of testimony from the medical profession and numerous clinical tests have definitely established Eatan as a unique restorative beverage for Invalids.
Issued in 2/6, 4/-, and 12/- bottles.
Special Terms to Hospitals.
Test sample and literature sent post free on application to:
A. DEHEZ, SURBITON, SURREY.

Dr. CHAUMIER'S
REINFORCED
Vaccine Lymph
Prepared in accordance with the Therapeutic Substances Regulations, 1927.
Supplied in tubes sufficient to vaccinate one person
at 8d. each.
Packing and postage 2d. each extra.

AN INDEX OF SYMPTOMATOLOGY

By Twenty-six Distinguished Contributors.

Edited by

H. LETHEBY TIDY, M.A., M.D.Oxon., F.R.C.P.Lond.,
Asst. Phys., St. Thomas's Hospital; Con. Phys., Royal Northern Hosp.

This book is intended to provide an account of the symptomatology of diseases. The general object has been to give a clear and reasonably full description of the clinical manifestations of each disease, without dwelling unduly on minor complications and variations.

"Should help considerably in the solution of difficult diagnostic problems. The articles, which cover all branches of medicine, surgery, gynæcology, and the specialties, are tersely written and well up to date . . . a volume worthy of the series to which it belongs."—B.M.J.

PROSPECTUS.

Objects.

THE Company has been formed for the purposes specified in its Memorandum of Association and in particular to acquire in London a site, build thereon, equip and manage a modern Medical Clinic and Nursing Home of the most approved scientific design and equipment.

Such a Clinic and Nursing Home is necessary to meet a long-felt need in dealing with paying patients. The Company's object is to provide an establishment in which there will be accommodation for (*a*) a group of consultants of established reputation, who will be able to avail themselves of the services of specialists with a complete equipment for comprehensive examination and diagnosis, which the advance of medical knowledge has made a necessity; and (*b*) a Nursing Home in which patients can be treated on these lines.

Provision has been made for 30 consulting rooms, and an essential part of the scheme is the establishing of a Nursing Home of 175 beds, in which patients can be examined, kept under observation, treated and nursed under the close supervision of specialists, acting in consultation with a patient's own medical practitioner.

A group of medical men have agreed, on completion and equipment of the Clinic, to take leases of consulting rooms and other premises in the building.

Ample space has been provided for occupation by specialists for the employment of the most modern methods of investigation and treatment, including Radium, X-rays, and deep X-ray Therapy, Actino-Therapy, Artificial Sunlight, the various forms of Baths, Electro-Therapy, etc., also for the installation of laboratories for Bacteriology, Pathology and Chemico-Physiology, and indeed every method which the most modern and up-to-date hospital provides. It is intended that each department shall be under the immediate supervision of a specialist.

While the poor of the community have at their disposal a fine equipment with a well-organised body of specialists in the many public Hospitals spread over the country, the advantages of organised team work are not generally available for those classes from which private patients come. It is intended to enable not only the well-to-do but people of moderate means to obtain these advantages and generally to provide for the needs of and harmonize expenses with the financial position of large sections of the middle class who are unable to bear the expenses of private investigation and treatment in existing Nursing Homes.

While there will be suites of rooms to meet the wishes of the wealthy classes, there will also be rooms where the total charges made will be based on a scale to accommodate patients with moderate means.

It is further intended that the fees quoted for accommodation in this Nursing Home shall so far as possible be inclusive. No gratuities to the staff will be permitted.

Shareholders in the Company will be provided with forms of recommendation in proportion to their holdings. Other considerations being equal, patients so recommended will so far as possible be given priority of admission.

Management.

Mr. Allan Hepworth has agreed to act as Managing Director. His wide experience, extending over many years, in the management of large and successful businesses in this country will thus be available for the Company. He will be assisted by an experienced resident Bursar and Staff. There will be a Medical Officer resident on the premises.

In order to secure close co-operation with the Medical Profession, there will be a Committee of Medical Consultants, who will act in an honorary advisory capacity to the Board of Directors.

It is intended that a representative of the medical group should be invited to join the Board after allotment.

Site and Design.

The site it is proposed to acquire is an ample and convenient one for the purposes of the Clinic and Nursing Home, covering an area of approximately 40,000 feet super, situated between Harley Street and Devonshire Place. The property will be held on a lease from Lord Howard de Walden for a term of 99 years, computed from 6th July, 1926, at a ground rent of £2,25 per annum.

A plan showing the site and proposed building thereon accompanies the prospectus.

Messrs. Humphreys, Limited, Building Contractors, of Knightsbridge, have agreed under contract (6 below to enter into a building agreement with the Company for the erection of the building to the design and specification of Mr. C. H. Biddulph Pinchard, F.R.I.B.A., within 18 months from possession of the site being given to the Contractors, for the sum of £300,000. This design is the result of close collaboration between the Architect and the group of medical consultants, and embodies the most up-to-date requirements of a modern hospital combined with comfort. Special care has been taken in the design and allocation of the bedrooms to ensure quietness.

Provision of Capital.

In addition to the amount to be provided by the issue of share capital, provisional arrangements have been made with the Equity and Law Life Assurance Society to advance, on completion of the building to the satisfaction of their Surveyor, a sum of £180,000, carrying interest at the rate of 6 per cent. per annum, reducible on punctual payment to 5½ per cent. per annum, to be secured by a mortgage or charge on the assets and undertaking of the Company, and by endowment policies for £180,000 maturing in 25 years, the annual premium on which will amount to £5,400.

Under the building contract the Company will provide the initial building cost of £120,000 from the subscription to the share capital and the building contractors, Messrs. Humphreys, Limited, agree to finance the balance of the agreed cost of construction up to the amount of the above advance of £180,000, pending receipt of this amount from the Insurance Company.

Contract (7) below provides for the lease of consulting rooms and other premises in the building for the residue then unexpired of the term of 99 years (less one day) from the 6th July, 1926, in consideration of the payment to the Company of a premium of £60,000 and an aggregate annual rental of £750.

Summarising the foregoing:—

The subscription, at par, of 175,000 Shares of £1 each will provide	£175,000
The advance on mortgage will provide	180,000
Premiums on grant of leases of Consulting Rooms will provide ..	60,000
Making a total cash capital available of	£415,000

Expenditure.

This amount will be applied towards the following:—

Estimated cost of building, furniture and equipment, including Architect's and Surveyor's fees	£317,000
Preliminary expenses (as below estimated, including underwriting and overriding commission brokerage and fees payable under contracts 8) and (10))	23,000
Purchase consideration payable for transfer to the Company of [illegible] Howard de Walden of lease rent, etc., paid)	11,300
G[illegible]'s premium on Endowment Policies	7,200
Leaving a balance for working capital, administration, and general purposes	26,500
	£415,000

Estimated Profits.

Estimates of receipts and expenses of the Clinic and Nursing Home have been arrived at by the Directors after close investigation in collaboration with Medical Consultants and individual authorities, and are summarised as follows:—

Receipts based upon 85 per cent. occupancy, which is considered conservative by medical advisers, rents, sundry fees, etc.	£133,000
Outgoings, viz., expenses of Clinic and Nursing Home, mortgage interest and premium on endowment policies for redemption of mortgage	87,600
Estimated net income available for dividend (subject to income tax and reserve)	£35,400

equivalent to 20 per cent. on an issued capital of £175,000.

The maturity of the endowment policies in twenty-five years will redeem out of profits £180,000 of the capital cost of the building, and after that time the Company's revenue will be relieved of the mortgage interest charge and premiums on the policies, together amounting to £15,300 per annum.

The minimum subscription on which the Company may proceed to allotment is as fixed by the Company's Articles of Association 7 Shares, but as the whole of the shares now offered for subscription have been underwritten under Contract (9) below the Directors will proceed to allotment on the closing of the list.

The Articles of Association provide as follows:—

The qualification of a Director shall be the holding of 100 shares in the Company. Any Director requiring a qualification may act before acquiring his qualification, but shall, if he accepts office, be bound to become the registered holder of the same within two months after his appointment, failing which he shall vacate office.

The Directors shall be paid out of the funds of the Company by way of remuneration for their services such sum as after paying and providing for Income Tax (but not Supertax) in respect of such remuneration according to the rate for the time being current will secure to the Chairman a net sum at the rate of £500 per annum, and to each other Director a net sum at the rate of £350 per annum. The Directors' remuneration aforesaid shall be deemed to accrue *de die in diem*. The Directors shall also be paid out of the funds of the Company by way of further remuneration for their services such further sum or sums as shall from time to time be determined by the Company in General Meeting, and such further remuneration shall be divided among them in such proportions and manner as the Directors by agreement may determine, and in default of such determination equally between them. In addition to the aforesaid remuneration the Directors shall be paid such reasonable travelling, hotel, and other expenses as they may incur in going to, attending, and returning from meetings of the Board, or of Committees of the Board, or General Meetings of the Company, or which they may otherwise incur in or about the business of the Company.

If any Director shall go or reside abroad on the Company's business or otherwise perform services, including service on a Committee of Directors, and whether of a temporary or continuing nature, for which, in the opinion of the Board, his ordinary remuneration as a Director may be inadequate, the Board may arrange with such Director for such special remuneration for the said services, either by way of salary, commission, or the payment of a stated sum of money or otherwise as they shall think fit, such special remuneration to be of such amount and to be payable during any period or periods, and to be in addition to any remuneration to which such Director would be entitled under the provisions of the last preceding Article, or otherwise as the Directors in their absolute discretion think fit.

The Directors may from time to time appoint one or more of their body to be a Managing Director or Managing Directors of the Company at such remuneration, either by way of salary, or commission on or participation in profits, or by any or all of these modes, as the Directors may determine, and either for a fixed term, or without any limitation as to the period for which he is or they are to hold such office, and may, subject to the terms of any contract between him or them and the Company, from time to time remove or dismiss him or them from office, and appoint another or others in his or their place or places.

The Directors may give to any officer or other person employed by the Company a commission on the profits of any particular business or transaction or a share in the general profits of the Company, such commission or share of profits to be treated as part of the working expenses of the Company.

A Director may hold any other office or place of profit in the Company in conjunction with his Directorship, and may be appointed thereto upon such terms as to remuneration, tenure of office and otherwise as may be arranged by the Directors, and a Director of the Company may be or become a Director of any company promoted by this Company or in which this Company may be interested as Vendor, Shareholder or otherwise, and no such Director shall be accountable for any benefits received as Director or member of such company.

The following Contracts have been entered into:—

(1) Memorandum of Terms, dated 11th May, 1925, between Colonel Edward Blount, C.B.E., of 23, Queen Anne Street, Cavendish Square, London, on behalf of the Right Honourable Thomas Evelyn Baron Howard de Walden and Seaford of 37, Belgrave Square, in the County of London, and F. G. Minter, of Ferry Works, Putney, providing for the grant of a Lease by Lord Howard de Walden of the site above referred to at the before mentioned annual net rental. Such Memorandum of Terms also provides as a condition of the grant of such lease that the proposed Lessee shall erect and construct the works mentioned in such Agreement to the satisfaction of the said Colonel Blount.

Lord Howard de Walden has through the said Colonel Blount signified his willingness to allow the Company to erect and construct in lieu of such works the building proposed to be erected and constructed by the Company as above mentioned subject to the said Colonel Blount first approving the final drawings and specifications.

(2) Dated 10th November, 1926, Memorandum of Transfer of the above Terms (endorsed thereon) from the said F. G. Minter to Major Arthur Frederick Vigor.

(3) Dated 28th April, 1927, Letter from the said Major Arthur Frederick Vigor to Christopher William Lucas.

(4) Dated 15th March, 1929, between Gerald Edmonds Compston of the first part, Alfred Ernest Webster of the second part and Major Arthur Frederick Vigor of the third part.

(5) Dated 8th April, 1929, between Christopher William Lucas, of 8, Manor House, Marylebone Road, London, and Major Arthur Frederick Vigor, of 57, Queen's Road, St. John's Wood, London, N.W., of the one part, and the Company of the other part, for the sale to the Company by them of the benefit of the Memorandum of Terms (No. 1 above) in consideration of the payment by the Company of £11,000, as to £7,250 to Christopher William Lucas (of which £3,500 is stated to have been expended for rent or otherwise in connection with the said Memorandum of Terms), and as to £3,750 to Major Arthur Frederick Vigor. The Company are also to indemnify such Vendors in respect of rent and outgoings as from the 11th October, 1928.

(6) Dated 8th April, 1929, between the Company of the one part and Humphreys Limited of the other part.

(7) Dated 8th April, 1929, between the Company of the one part and Robert Hugh Spencer of 2, Park Mansions, St. John's Wood, N.W., of the other part, providing for the grant to him or his approved nominees, on the completion and equipment of the building proposed to be erected and constructed by the Company, of a lease or leases (for the then unexpired residue of the term of 99 years (less one day) from the 6th July, 1926, in consideration of the payment to the Company of a premium of £60,000 and an aggregate annual rental of £750) of 30 consulting rooms, part of such building together with the use of waiting rooms and other premises in connection therewith and other amenities usual in the subletting of consulting rooms, including the provision of laboratories at a reasonable rent and for a term to be agreed.

(8) Dated 8th April, 1929, between Townsend and Ridsdel Limited of the one part and the Company of the other part, whereby the Company agrees to pay to Townsend and Ridsdel Limited a fee of £4,500 in consideration of the services of the latter in connection with the formation and incorporation of the Company and negotiating the arrangements with Messrs. Humphreys Ltd. and the Equity and Law Life Assurance Society.

(9) Dated 8th April, 1929, between the Salisbury Trust Limited of the one part and the Company of the other part, whereby the former agrees to subscribe or find responsible subscribers for the above issue of 175,000 shares for an underwriting and overriding commission payable by the Company of 3 per cent. and 1 per cent. respectively on the nominal amount of such shares.

Various sub-underwriting agreements have been entered into to which the Company is not a party.

(10) Dated 8th April, 1929, between the Company of the one part and the Salisbury Trust Limited of the other part, whereby such Trust agrees (*a*) to supervise and attend to the advertising, circulation and distribution of this Prospectus and to make all necessary arrangements with bankers, brokers and others for dealing with this issue in consideration of the payment by the Company to such Trust of a fee of one thousand guineas, and (*b*) to bear and pay the preliminary expenses of the Company down to the first general allotment of the Company's shares (excepting underwriting and overriding commission, brokerage and *ad valorem* duty on the sale to the Company and the fee payable under contract (8) above), in consideration of the payment by the Company to such Trust of the sum of £10,000.

(11) Dated 26th March, 1929, leter from the Equity and Law Life Assurance Society to the Company, providing for the advance by the Insurance Company as above mentioned.

(12) Dated 8th April, 1929, letter addressed by the Company to the Equity and Law Life Assurance Society accepting the terms of the last-mentioned letter.

(13) Dated 8th April, 1929, between the Company and Allan Hepworth for the appointment of the latter as Managing Director during construction of the Building and preliminary organisation period up to the date of opening at a fee of £1,500 and thereafter upon terms to be agreed.

Captain H. S. M. Harrison-Wallace, one of the Directors, is a Director of Townsend & Ridsdel, Ltd., and holds one share in that Company out of an issued capital of 5,000 shares of £1 each, and is also entitled to a participation of 6 per cent. in the net annual profits of Townsend & Ridsdel, Ltd.

The following Directors have respectively sub-underwritten Shares of this issue as follows:—Mr. Allan Hepworth 1,000 shares, Mr. B. H. Binder 500 shares, and Captain Harrison-Wallace 500 shares, each receiving therefor a commission of 3 per cent.

The preliminary expenses (excluding underwriting and overriding commission brokerage and *ad valorem* duty on the sale to the Company and the fees payable under Contracts (8) and (10) above) are estimated at £10,000.

A copy of the Memorandum of Association of the Company, with the names, addresses and descriptions of the signatories, is printed on the back and forms part of the Prospectus.

A brokerage of 3*d.* per share will be paid on all shares allotted in respect of public applications bearing the stamp of any Broker, Banker or other authorised Agent.

Applications for Shares should be made on the Form accompanying this Prospectus and forwarded with the amount payable on application to the Bankers, Lloyds Bank Limited, 20, King William Street, London, E.C., or any Branch of the Bank. If no allotment is made the application moneys will be returned in full, and where partial allotment is made the surplus application moneys will be credited in reduction of the amount payable on allotment, and any excess returned to the applicant.

Interest at the rate of 10 per cent. per annum may be charged on instalments in arrear, and failure to pay any instalment when due will render the shares and the previous payments liable to forfeiture.

Copies of the Memorandum and Articles of Association and of the above-mentioned Contracts can be inspected at the offices of the Solicitors to the Company at any time during business hours on the days on which the subscription list remains open.

Prospectuses and Forms of Application can be obtained at the registered office of the Company or from its Bankers, Brokers, or Solicitors.

Dated 8th April, 1929.

This Application Form may be used.

THE CIVIL SERVICE CO-OPERATIVE TRUST, LIMITED.

Directors:
Sir HENRY J. GIBSON, K.C.B. (Chairman), late Comptroller and Auditor General.
D. H. BOGGIS-ROLFE. Major L. Sr. JOHN COLLEY. A. CARSON ROBERTS. J. CLIFFORD ROWE, J.P. Mrs. A. SAMSON.
Auditor: Sir GILBERT GARNSEY, K.B.E. (Public Auditor, appointed under the Industrial and Provident Societies Act, 1893).
Bankers: BARCLAYS BANK, LIMITED.

You are invited to become a Shareholder of this Investment Trust. As its title implies, it was formed with the particular view of providing a sound medium for the investment of the savings of Civil Servants, but there is no restriction of class, and any person may become a Member. A number of Medical Practitioners are Members.

This Trust possesses a Board of Directors which should give the Members complete confidence that there is no unsound treatment or waste of funds. It includes men of experience and distinction in finance, in the special work of Investment Trusts, the investigation of securities and accounts, and the advising of Companies, Trustees and individual investors upon their investments.

The Civil Service is represented by three men who have held the leading posts in the audit and supervision of our National, Local Government, and National Insurance accounts respectively.

As in the case of any good scheme for combined investment, the Trust provides for a good return and the prospect of an increasingly high yield with a degree of safety not obtainable by direct investment. The funds are invested in a large number and great variety of securities. The individual Shareholder, therefore, in respect of his one small holding is effecting a sort of insurance by spreading his risks over a large number of concerns.

No deduction of Income Tax is made from the dividends. Hence Shareholders are freed from the trouble and the risk of loss connected with tax reclaims. Shareholders liable to make Income Tax returns must of course disclose these dividends.

The Shares of the Trust are all of one class and of 2s. denomination with 1d. a share entrance fee. The smallest subscription allowed is of 10 shares, costing £1 0s. 10d., and the largest of 2,000 shares, costing £208 6s. 8d. Any sum between these two limits may be subscribed at the same rate in units of £1 0s. 10d. (10 shares), until the entrance fee is raised. Investment at the minimum rate is still available. Shares rank for dividend as from the first day of the month following the date on which they are allotted.

The Board is prepared to facilitate the sale of any shares of which a Member may desire to dispose so that the seller may, so far as practicable, benefit by any enhanced value.

The Trust was registered October, 1928, and did not start active existence until 25th January, 1929, since when it has had no blank day in the matter of subscriptions.

THIS APPLICATION FORM MAY BE USED. (15)

To the Directors of **THE CIVIL SERVICE CO-OPERATIVE TRUST, LIMITED,**
341, WINCHESTER HOUSE, LONDON, E.C.2.

I, the undersigned, hereby apply for.....Shares of 2s. each in the above-named Trust, subject to the Rules of the Trust. I enclose a remittance for £.....:.....s.....d., being payment in full for such Shares, together with an entrance fee of 1d. per Share, and I agree to hold the same or any lesser number which you may allot me.

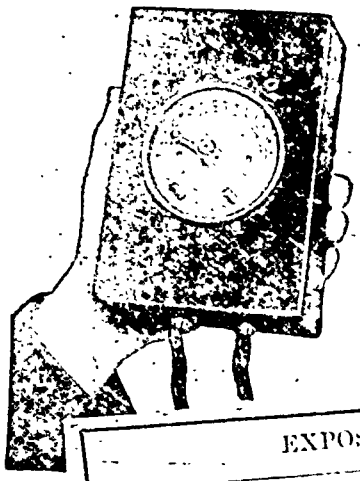
Without previous experience— you can make your own Radiograms!



THERE are uses for X-rays in almost every practice. No longer need the medical man be without. The "METALIX-PORTABLE" is within the reach of every practitioner, and successful radiograms can be taken without fuss or bother. Nor are the advantages of X-ray diagnosis confined to the consulting room alone. Wherever there is electric light—there you can use the "METALIX-PORTABLE."

EXPOSURE TABLE.

Subject.	Intensifying Screens.	
	None.	Two Screens.
Hand	2 secs.	—
Elbow	3 ,,	—
Foot	4 ,,	1 sec.
Tibia	5 ,,	1 ,,
Shoulder Joint	9 ,,	1½ secs.

HEALTH THROUGH TOWN WINDOWS

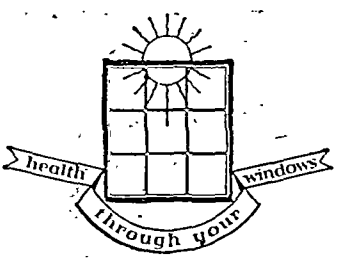
Does the smoke pall shut out the ultra-violet rays?

It has been said that glass which admits the ultra-violet rays is of little use in towns since the effective rays are stopped by the pall of smoke which hangs over all industrial areas.

The regular records now being taken of the measurements of ultra-violet light in certain cities, provide convincing evidence of the presence of biologically active ultra-violet rays in sufficient proportion to be of the utmost value to the health of the town dweller.

The "Vita" Glass window offers a practical method of utilising the smaller amount of ultra-violet light available in towns. It is being used in smoky cities with marked beneficial effects to those who live and work indoors.

Some important data, collected from recent research work relative to smoke and ultra-violet energy has been published by the "Vita" Glass Marketing Board. A copy of this pamplet, entitled "Are the Ultra-violet Rays Present in Towns?" will be sent to any medical man on request. Write to the "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C.2.



"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

Gaymer's CYDER

GAYMER'S WAS FIRST SHOWN AT THE BRITISH MEDICAL ASSOCIATION EXHIBITION OF 1898.

WM. GAYMER & SON, LTD., ATTLEBOROUGH, NORFOLK.

Prescribed in numerous cases *of nervous and heart disorders, also rheumatic conditions, etc.*

The active substances of the extracts from cone bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

Prescribe 'Mistol' for the Nose and Throat.

MISTOL has proven especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Mistol consists of menthol, eucalyptol, and camphor carefully combined in proportions recommended by leading nose and throat specialists. A specially prepared petroleum base keeps the soothing, healing ingredients in direct contact with the mucous membrane for a considerable length of time. Moreover, it prevents it being easily washed away by the natural secretions.

Mistol and the Mistol Dropper are a real advance in nose and throat therapy. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. Unlike douches, Mistol avoids any possibility of sinus trouble. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Sold in original sealed cartons containing a—

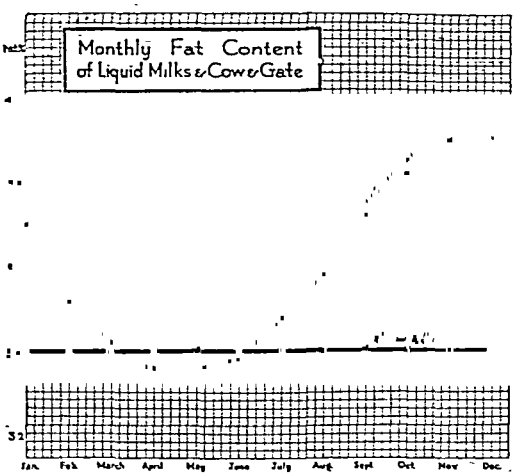
A RELIABLE BASIS



The above shart shows the large fluctuations in the fat content of liquid milks throughout the year, as compared with the unvarying fat content of COW & GATE, which is based on the fat content of average healthy Breast Milk.

Fat content in COW & GATE reconstituted (1 in 8) 3.4%

Fat content in average Breast Milk 3.3% — 3.5%

This is ONE of the many reasons why COW & GATE is one of the safest and most reliable alternatives when breast-feeding fails, and why it affords the most reliable basis for Infant-feeding modifications.

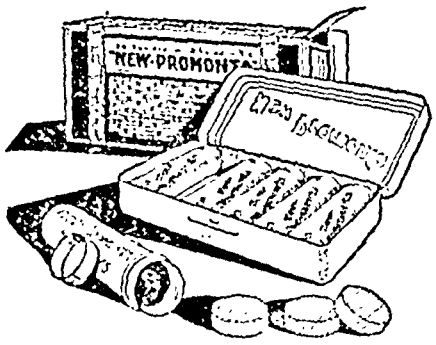
THE WEST SURREY CENTRAL DAIRY CO., LTD., GUILDFORD, SURREY.

THE ACTION OF LIPOIDS IN CELL-METABOLISM

The importance of Lipoids in restoring active and healthy cell metabolism is appreciated by the Medical Profession. Moreover, the now established fact that Lipoids have a definite organ specificity makes their proper administration, in all cases where Lipoid deficiency is diagnosed, a scientifically accurate treatment.

In "NEW-PROMONTA" the Nerve Lipoids, the Phosphatides and Cholesterols are maintained at full value by a special process of preparation which also ensures their combination in the exact proportions present in the living cells of the nerves and brain. "NEW-PROMONTA" is therefore a specific nerve food of established value in the treatment of nervous complaints.

The further addition of such nutritives as Iron, Haemoglobin, Lime, Albumins and the Vitamins A, B, D and E in an easily assimilated form makes "NEW-PROMONTA" a very excellent tonic food and body builder, especially desirable in cases of malnutrition, for counteracting the after-effects of illness and during convalescence.



TO TEST "NEW-PROMONTA."

A trial supply of "NEW-PROMONTA," together with a collection of authoritative data on its composition and the tests to which it has already been subjected, will be sent post free to any Doctor, Clinic, or Hospital on application.

"NEW-PROMONTA" in Tablet form is supplied in handy boxes containing 54 tablets at 3/6. Each box includes a metal container for the pocket which holds a day's supply. "NEW-PROMONTA" in Powder form is supplied in sealed air-tight boxes of ½ lb. at 3/- and ¼ lb. at 5/6.

ALOCOL

Colloidal Hydroxide of Aluminium

Successful Treatment of Hyperchlorhydria

"Alocol" is a triumph of colloidal therapy, because it is completely free from the marked disadvantages associated with the usual alkaline medicaments.

Take bicarbonate of soda as an example. When in the stomach it is transformed into sodium chloride—the very product which goes to the formation of hydrochloric acid. To combat hyperacidity by such means is to create a vicious circle.

Note the different action of "Alocol." It absorbs excess of hydrochloric acid and the acid-containing mass is finally evacuated from the lower bowel. This colloido-chemical absorption removes from the system the causative acid radicle (Cl) instead of merely neutralizing it. "Alocol" thus prevents reabsorption, accumulation, and consequent recurrence of the symptoms of the disease.

"Alocol" leaves intact the acid reaction of the gastric juice and its normal digestive and bactericidal functions. It is the remedy *par excellence* for hyperchlorhydria. The absorbent, healing, and sedative properties of "Alocol" also prove of the greatest value in successful treatment of the more serious manifestations, such as gastrectasis, gastrelcosis, pyloric and duodenal ulcers, infective enteritis, etc.

Complete chemical history of "Alocol" with convincing clinical reports and supply for trial, sent free to physicians on request.

Recent Laboratory Work in Connection with Lysolats

The searching tests to which the solid form of lysol has been subjected have confirmed the favourable medical opinion of the bactericidal value of Lysolats.

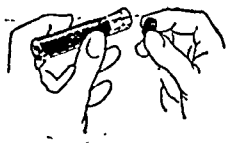
Experiments have been carried out under the Rideal-Walker and Martin-Chick technique by such authorities as the Royal Institute of Public Health Laboratories, London, the Pathological Laboratories, Harley Street, W., and the Clinical Research Laboratories, Adelphi, W.C.

Abroad, similar tests have been made by the Pasteur Institute, Paris, the Microbiological Laboratories of the University of Nancy, and Professor Huynen of the State Veterinary University of Brussels.

It has been determined that a 1 per cent. solution of Lysolats will arrest the development of most pathogenic organisms in 2 seconds and will completely destroy them within 40 to 50 seconds.

A comparative test in different dilutions of Lysolat and Carbolic Acid on the following organisms—B. Pyocyaneus, B. Bang, B. Typhosus, B. Coli, B. Pneumococci, B. Staphylococci—shows that the bactericidal power of Lysolats is 20 times more efficient than that of ordinary Carbolic Acid.

Lysolats
PATENT 118667 (LYSOL TABLETS)



For Personal Use by Medical Men.

Many doctors now use Lysolats when washing their hands. One tablet rubbed between the palms with plenty of water is a valuable safeguard.

* * *

Lysolats are packed in handy tins which are particularly suitable for carrying in the satchel. The tins contain 40 and 80 tablets (at 1/3 and 2/- respectively). There are also tins of 1,000 tablets.

* * *

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney Street, London, S.E.1.

Curative Treatment of
Pernicious Anæmia

LIVER EXTRACT B.D.H.

The administration of Liver Extract is to-day recognised as the routine treatment of pernicious anæmia. This new treatment is yielding very satisfactory results and is giving 'inestimable relief.'

(Report of the Medical Research Council for the year 1927-1928, p. 13.)

Physicians have been quick to appreciate the value of this simple method of treating a disease which has hitherto been regarded as incurable.

Liver Extract B.D.H. is a freely-running powder of such concentration that a very small bulk is equivalent in therapeutic value to ½ lb. of fresh raw liver.

The potency of Liver Extract B.D.H. is remarkable; a typical clinical report on a case under treatment shows a rise in the blood count from 890,000 to 3,960,000 within one month.

Liver Extract B.D.H. is stable, is exceedingly easy to administer and is pleasantly flavoured. It is prepared by a special process tested and approved by the Medical Research Council. Physicians realise that when the B.D.H. product is prescribed their patients receive a uniformly reliable product.

B

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

The Source of NOURISHMENT

VITAMIN B

Outstanding advantages of HOVIS

Of all kinds of bread consumed to-day, HOVIS is richest in Vitamin B, which encourages growth and increase of weight. Bulk for bulk it supplies a greater amount of nourishment.

HOVIS combines all the benefits of white flour with 25 per cent. of the wheat germ, the part richest in the vitamin, added.

Compared with other cereals, the Vitamin B content of milling products and yeast in 100 g. dried bread is as follows:

White Bread	200
Wholemeal Bread ...	1,450
HOVIS Bread	2,600

The great value of HOVIS is that it contains all the elements of a complete food; it is universally liked, and containing no bran is easily absorbed.

It is also most economical, the quantity necessary to furnish sufficient nourishment being very small.

Were HOVIS to form a part of everybody's daily diet the nation would undoubtedly be better nourished.

THE FRENCH NATURAL MINERAL WATER

VICHY-CELESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. **Vichy-Celestins**, by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

INGRAM & ROYLE, LIMITED,

BOOTS PRODUCTS

"VITAMALT" Reg.

RICH IN ESSENTIAL VITAMINS A, B, C, & D.

Vitamins have gone beyond the experimental stage. Modern research work has demonstrated the vital necessity for the various vitamins against anti-infective processes, rachitic conditions, and deficiency diseases, and in providing for the human system a very necessary adjunct in the maintenance of good health. Vitamalt is the only preparation of its kind which is guaranteed to contain vitamins A, B1, B2, C, and D, and it has been demonstrated that Vitamalt assists the metabolic processes, promoting normal development of bone and tissue, and ensuring correct assimilation of calcium. In Vitamalt, vitamins are incorporated in the proportion which science has indicated as the most suitable for average conditions.

Price 1/9 and 3/= per jar.

CAPROKOL

(Hexyl-resorcinol B.D.H.)

Caprokol gives immediate symptomatic relief in infections of the urinary tract; this fact is appreciated by physician and patient alike.

Caprokol treatment ensures hours of continuous sleep (unbroken by the necessity for frequent micturition), cessation of pain, and subsidence of fever. The patient's appetite increases, and, as the suffering decreases, the general health rapidly improves.

The final result of Caprokol therapy, in practically every case, is the complete disinfection of the urinary tract and restoration to normal health.

Intestinal Disinfection

ALLERGIC CONDITIONS & PROTEIN SENSITISATION

MUCH attention has of late been directed to states in which the subject has become sensitised to some substance, and on exposure to the same substance reacts in a characteristic manner.

The substances which may sensitise are very varied (*e.g.*, animal dandruff and hairs, plant pollens and hairs, animal and vegetable proteins of foods, bacteria and their products) and the reaction may take the form of epileptic attacks, fainting fits, skin eruptions, asthma, etc.

In many instances the sensitisation is produced by bacteria or their products in the bowel, and by the exhibition of an efficient intestinal disinfectant the subject is cured. This has been found to occur in many cases of asthma, eczema and other skin diseases.

The best of all intestinal disinfectants is Kerol, which acts as a specific cure in many of these cases.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

WRIGHT'S LYSOL

BRITISH MADE :: :: BRITISH OWNED

A handy graduated measure is provided with every bottle.

All your patients need know about Lysol is the name "Wright's"

If they get Wright's, they are getting a pure, highly refined Lysol—a British made product by a British owned firm who have enjoyed an unblemished reputation with the Medical Profession since 1852.

Wright's Lysol is analytically controlled by the Rideal-Walker test, and in proper dilution gives certain results. Independent laboratory tests prove its superior grade, strength, and purity. It does not irritate or roughen membranes.

For your patients' protection, tell them always to insist on "Wright's" Lysol—made by the makers of the world famed *Wright's Coal Tar Soap.*

Strects 65.

INSULIN "A.B."

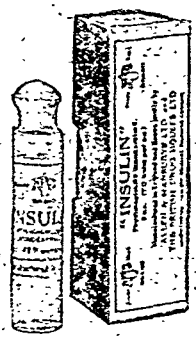
TRADE A B MARK Brand

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

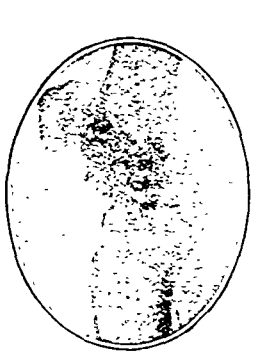
"IODOLYSIN"

Trade Mark

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies



Radiograph of Knee-joint in Rheumatoid Arthritis

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages.

Ready Solubility in water. Well tolerated. Absence of local reaction on injection

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Psychotherapy and the General Practitioner

"We must not lose sight of the fact that people have faith in local treatment, that it appeals to their imagination and that—just to this extent—it carries with it *psychotherapeutic potency*. From all these considerations may be coined the therapeutic maxim: *'Use appropriate topical treatment in all conditions in which it is justifiable'.*"
B. Fantus, M.D. ("The Technic of Medication", A.M.A. Press, 1926).

FROM time immemorial psychotherapy has played a large, though often unrecognized, part in all successful treatment. The application of the general principles of psychotherapy includes all measures, apart from the physical, of influencing the patient and of helping him to overcome disease.

The sensation of pain certainly belongs within the compass of the psychotherapeutist. The pain sensation is exhausting, the fight against the pain decreases the resistance of the individual, and interferes with the normal flow of the mental life. The psychotherapeutic effort, directed toward removing the source of the pathologic disturbance, inhibits the pain by filling the mind with agreeable feelings and pleasant ideas, until the normal equilibrium is again restored.

Antiphlogistine

is not entirely based on its psychotherapeutic potency. In countless numbers of cases, its timely application has really served to bring more rapid relief from the physical pain, together with obliteration of the concomitant mental distress. The ever-increasing use of this plastic, analgesic, hygroscopic dressing by the Medical Profession the world over is the best evidence of its merits in the treatment of superficial and deep-seated inflammatory and congestive conditions.

Health Aspects of Vita-Weat

In cases of diet regime a readily acceptable and beneficial alternative to ordinary bread will be found in Vita-Weat—the whole-wheat British crispbread.

The "Lancet's" Report.

Being made from 100% stone-ground whole wheat, Vita-Weat preserves all the vitamins intact. The *Lancet* reports that Vita-Weat is "a valuable foodstuff, more particularly in respect of its content of Vitamin B." Vita-Weat is also rich in Vitamins A and D, in proteins, and in the valuable mineral salts so necessary to health.

Extremely Palatable.

Vita-Weat is extremely palatable, possessing a delicious "crunchiness" and ripe-corn flavour. Its crispness encourages mastication and so promotes a healthy condition of the teeth and gums.

High Calorie Value.

"The calorie value of Vita-Weat," says the *Practitioner*, "is 2,132 per lb., which may be compared with the calorie value of fresh white bread, namely 1,210 per lb." It will thus be seen that Vita-Weat possesses a high physiological fuel value.

To Counteract Constipation.

The branny scales of Vita-Weat act as a stimulant to normal peristalsis, whilst not exerting an undue irritative effect on the intestinal mucous membrane.

To Prevent Obesity.

The starch granules in Vita-Weat are thoroughly disintegrated. No starch passes unconverted into the body to cause obesity and indigestion. Vita-Weat is "completely assimilable," states a report of the Royal Institute of Public Health.

ROCK BEARING INSCRIPTIONS OF ASOKA.—Asoka was a great pioneer in the realm of ethics. He directed his people's thoughts towards spiritual aims and taught that right conduct should be man's chief desire. His idea of right conduct may be gathered from the following excerpts taken from the fourteen edicts inscribed upon the rock here reproduced: "Father and Mother must be harkened to; similarly, respect for living creatures must be firmly established; truth must be spoken. The teacher must be reverenced by the pupil, and fitting courtesy must be shown to relations." "Here no animal may be slaughtered for sacrifice . . . Formerly, in the kitchen of His Sacred and Gracious Majesty the King, each day many thousands of living creatures were slaughtered to make curries. But now, only three living creatures are slaughtered for curry daily, to wit, two peacocks and one antelope . . . Even those three living creatures shall not be slaughtered in future." "Even for a person to whom lavish liberality is impossible, mastery over the senses, purity of mind, gratitude, and steady devotion are altogether indispensable." "In the ceremonial of piety are included proper treatment of slaves and servants, honour to teachers, gentleness towards living creatures."

VITAMINS A, B & D
HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession—a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

A Post-Graduate Lecture
ON
THE TREATMENT OF CANCER OF THE RECTUM WITH RADIUM.

DELIVERED AT ST. MARK'S HOSPITAL
BY
SIR CHARLES GORDON-WATSON, K.B.E., C.M.G., F.R.C.S.,
SURGEON TO ST. BARTHOLOMEW'S HOSPITAL AND TO ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM.

RADIUM IN SURGERY.

THE publicity that has been given to radium treatment by the recent cancer conference has resulted in a sudden awakening on the part of the public and the profession to the work that has been done and is going on quietly in a scientific spirit of research. There is some danger that a sudden wave of enthusiasm may result in the indiscriminate distribution and use of a dangerous surgical weapon if supplied to and employed by workers who have not studied the subject and are not able to employ it on a research basis. There is at present no general agreement or standardization as to dosage or methods of application. Distant therapy with a larger volume of radium has barely commenced in this country, and the supply of radium has not at the present time allowed a great many workers to try out the comparative merits of emanation seeds and radium needles. In short, there is some danger that the treatment of cancer with radium may be dragged from the nursery before its time.

RADIUM IN CANCER OF THE RECTUM.

Progress in the results of operative treatment of cancer of the rectum has been so great in the last ten years that we can now speak confidently of a probable cure in an early case when the patient is a good subject for operation. Unfortunately the great majority of cases reach the surgeon when the operable stage is past.

For many years attempts have been made to cure such cases by radiation, either by deep x-ray therapy or by the insertion of a tube containing some 50 mg. of radium into the lumen of the growth. In sporadic instances growths have been destroyed on these lines. As far back as 1910 I was associated with a case which was cured in this way by Dr. Finzi, and the patient remained free from rectal trouble until his death some ten years later from another cause. Such a result as this was found to be quite exceptional. In many instances severe burns resulted and the sufferings of the patients were increased rather than relieved.

Early in 1925 I visited the clinic of Dr. Neumann in Brussels and was much impressed with his results in the treatment of carcinoma of the rectum by needling the growth after free exposure from behind, and I at once set to work to follow his technique. In November, 1927, I reported my results of needling by open operation to the Sub-Section of Proctology at the Royal Society of Medicine, and gave an analysis of the first fifteen cases. I was able to show that both operable and inoperable growths can in some instances be destroyed completely and without risks of radium burns, and that the patients can be restored to apparent sound health provided that they submit to colostomy. I showed two cases of apparent cure up to date. Since that time I have gained further experience by the open operation from the perineum, having treated over thirty cases by this method, with some very encouraging results.

More recently I have embarked on intra-abdominal treatment of high rectal growths, and I have treated a series of cases by implantation of radium needles and also platinum or gold filtered radon seeds both into the growth and into the areas of lymphatic spread in the meso-rectum and meso-sigmoid. After the introduction of radium, colostomy is performed, but the bowel is not usually opened until the needles are removed a week later. When seeds are used they are not removed, and the colostomy can be opened at any time.

In some instances I have irradiated growths both from above and, later on, from below at a second operation, employing seeds screened with 0.5 mm. platinum either through the skin of the perineum directed by a finger in the rectum or through the lumen of the bowel, and also per vaginam.

In the more recent cases of low growths submitted to the open operation from the perineum I have attacked the glandular areas from the abdomen at the time of the colostomy, using seeds when available, and otherwise needles. In one instance of a small growth I inserted seeds directly into a low-lying growth without performing colostomy, and secured complete regression of the tumour.

All but one of the open perineal operations have been submitted to colostomy, and in only one case treated by the abdominal route has colostomy been avoided. This patient was shown quite recently at the Royal Society of Medicine, and the notes of the case are worthy of record. The following is the history of the case.

A postman, aged 44, was admitted with an annular growth at the junction of the pelvic and perineal portions of the rectum, which was fixed to the base of the bladder and to the sacrum. The abdomen was opened and the growth barraged with nine needles containing a total of 20.5 mg. left in position for 115 hours (2,357 mg. hours). The pelvic colon was fixed outside the abdomen in preparation for colostomy. The patient, however, with the help of a liberal supply of paraffin, continued to evacuate his motions with comfort per anum after the radium was removed, so that the opening of the colostomy was postponed, and in the end was never carried out.

The patient returned to work soon after discharge from hospital and has remained in uninterrupted good health since (for over a year). Sigmoidoscopy shows a narrowed lumen but no evidence of growth.

The Perineal Operation.

The technique of the perineal operation consists, in brief, of removal of the coccyx, division of the raphé at the junction of the levatores ani, and free exposure of the ampulla of the rectum. The lines of lymphatic spread along the superior, middle, and inferior haemorrhoidal arteries are barraged, and subsequently the growth is uniformly needled, so that all parts of the growth receive as far as possible uniform radiation of not less than 1 mg. per c.cm. In the female the anterior portion of the growth is barraged through the posterior vaginal wall. The time factor is usually ten days, and from 30 to 60 mg. of radium are employed according to the size of the growth. The wound is packed with flavine gauze and kept moist by the Carrel-Dakin method, the skin wound being temporarily closed until the radium is removed. The wound is slow to heal, and usually takes about six weeks to close. Reaction is usually slight, but occasionally in feeble individuals a heavy irradiation is followed by extreme weakness, loss of appetite, and vomiting—symptoms which soon subside after removal of the radium.

In advanced cases very little change can be noted in the size of the growth under six to eight weeks, and the most marked changes occur in the third and fourth months, but usually after a short period of increased secretion of mucus the local symptoms are relieved and haemorrhage and tenesmus are checked. The most striking feature in these cases is that as soon as the immediate effects of the operation and radiation have passed off the general condition of the patient improves rapidly, and even when no marked diminution can be noted in the size of the growth the patient recognizes that his condition has improved enormously.

In some cases when the perineal barrage has failed to act on all portions of the growth I have used a 50-mg. heavily screened platinum tube in the lumen of the rectum as a supplement to needling. This has been inserted into a slot cut in a solid lead rod enclosed in rubber tubing so that its action is limited to the area requiring treatment, and other portions of the lumen are protected.

Irradiation Prior to Operation.

There can be no doubt that in some instances an inoperable case can be rendered operable by the preliminary use of radium. In May, 1926, I used radium for a growth of the anterior half of the rectum which was adherent to the uterus and had perforated into the vagina. In February, 1927, the perforation had closed, the growth was much reduced in size and was no longer fixed to the uterus, and

the general condition of the patient had improved enormously. In March, 1927, I excised the rectum, and the patient is alive and well to-day.

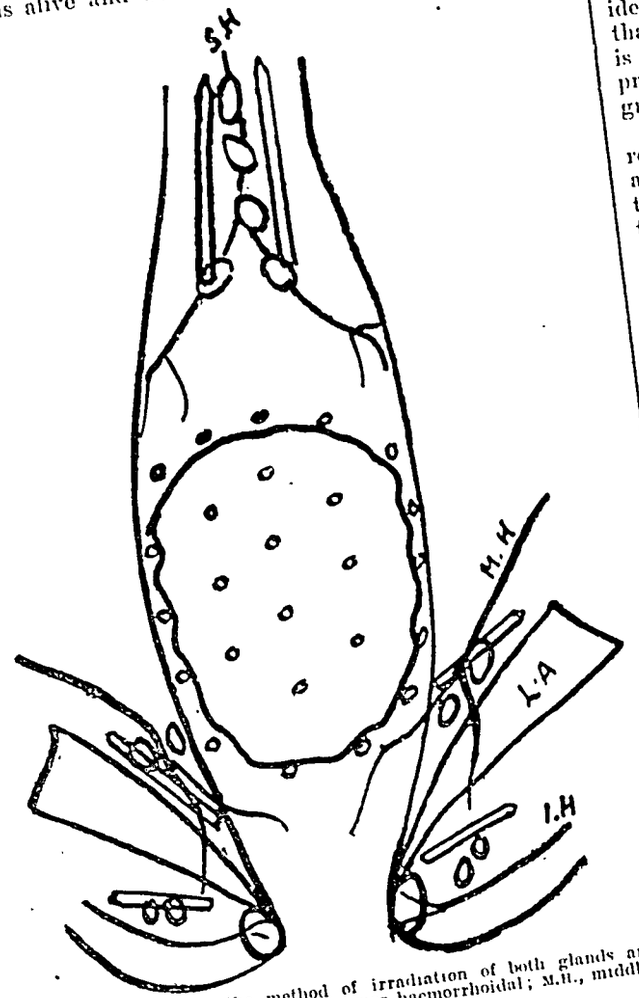

FIG. 1.—Shows the method of irradiation of both glands and growth from behind. S.H., Superior haemorrhoidal; M.H., middle; I.H., inferior; L.A., levator ani.

In several instances I have inserted radium per abdomen at the time of colostomy to attack the glandular areas prior to perineal excision for an operable growth.

Radium for Recurrence.

In the past a local recurrence of carcinoma following excision of the rectum has seldom been amenable to successful surgery. In some instances favourable response to deep x rays has been noted, but these results have been of a temporary nature. I have been able to treat a few of these patients quite effectively with needles combined with external radiation on Columbia paste. No patient has been under observation long enough to express an opinion as to cure, but results so far have been much more encouraging than could have been anticipated.

THE RELATIVE VALUES OF SURGERY AND IRRADIATION.

I do not think that any of us who are in the habit of operating on cancer of the rectum have any doubt in our minds that we can cure cancer of the rectum in the early stages (except in the very young) by means of surgery, provided that the patient will submit to colostomy and can survive the radical operation. If early diagnosis was the rule instead of the exception the surgical results of radical cure would stand comparison with those of cancer in any other region of the body. The reason for this confidence is that, save in exceptional circumstances—for example, in very young subjects—glandular and visceral metastasis occurs late in the disease.

Radical surgery for cancer of the rectum may be criticized on the score of mutilation in that a colostomy is essential and a reproach to surgery. Although I do not regard a well-managed colostomy as a great handicap in life—and I can produce many professional and business men, who follow their avocations with little hindrance, to support this view—I do feel that when we see what can be done with the tongue, for example, we ought to explore the field of radium to the utmost in an endeavour to supplant radical surgery.

I have on many occasions expressed my views as to the ideal surgical treatment of rectal cancer, and I still hold that colostomy followed by the modern perineal excision is the best procedure for all mobile growths in the rectum proper, reserving the abdomino-perineal operation for growths at or above the recto-sigmoidal angle.

The time may come—it may even be within measurable reach—when we shall have such certain control of the action of radium that we shall be able to say, as it can at the present time, I believe, be said of many cancers of the tongue and cervix: "This case, though suitable for a radical surgical operation, can be cured with greater certainty, with less risk, and—greatest boon of all, if it comes—without any permanent disability, with radium."

Until we are in a position to measure the action of radium with some accuracy, to be able to say with confidence that a given dose of radium administered in a given way for a given time will produce a certain result, we are, I think, in duty bound to advise radical surgery, mutilating though it is, in preference to radium for the operable case. Where, however, as sometimes happens, the growth is operable, but the patient is considered unsuitable for radical surgery on other grounds, then I believe radium holds out great prospects of cure, and should always be employed when available.

It is quite possible that in the near future rectal irradiation may be so regulated as to offer as high a percentage of cures, *in early cases*, as by operation and with less risk, and in a certain number without the inconvenience of colostomy. For the inoperable case, provided that there is no secondary perirectal sepsis, invasion of the bladder, or metastasis in the liver, radium should certainly be recommended.

In recent years experience with radium in the treatment of carcinoma of the tongue has produced such remarkable

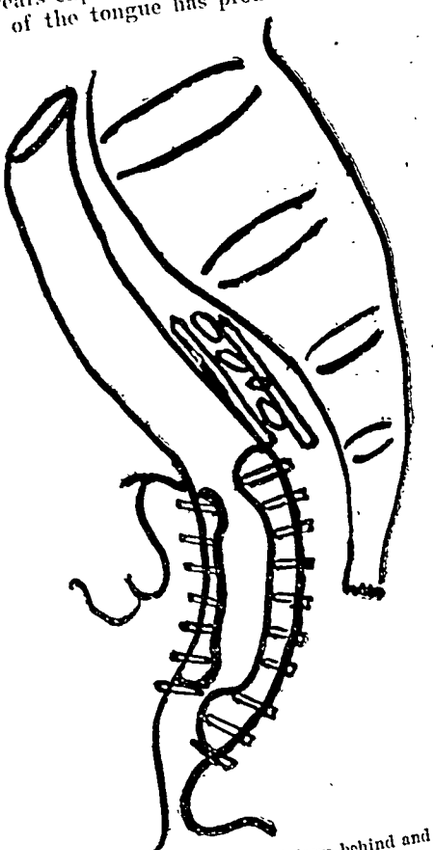

FIG. 2.—Shows needles employed from behind and per vaginam.

results that those who practise radium therapy have for some time past ceased to excise the tongue. Carcinoma of the cervix uteri stands on the same footing, and, judging by the results which are now being obtained with radium in the treatment of cancer of the breast, it will not be long

before those surgeons who have access to, and experience with, radium will cease to amputate the breast. I hope to see the time when the same can be said of excision of the rectum.

When passing in review the results of my work with radium during the last four years I do not doubt that, with increasing experience, we shall be able to cure year by year a higher percentage of inoperable cases, and I am satisfied that with judicious selection of cases we can assist those who have passed beyond the hope of cure by alleviating their symptoms and prolonging their lives.

CONSTRUCTIVE EPIDEMIOLOGY.

BY

SIR RONALD ROSS, K.C.B., K.C.M.G., F.R.S.,

DIRECTOR-IN-CHIEF, ROSS INSTITUTE AND HOSPITAL FOR TROPICAL DISEASES, PUTNEY HEATH, S.W.

THE services of medical men, pathologists, and parasitologists are required for investigating the nature of any disease, whether it occurs in isolated cases or in epidemics; but mathematicians are needed to examine the cause and *progress of the latter—just as any skilled observers may* trace the path of a planet, but careful mathematical computations must be made into the forces concerned in its movement. Such computations may be either deductive (*a posteriori*), or constructive (*a priori*). By the former we seek to deduce the laws from the observed facts; in the latter we assume what we suppose are the laws, and then try to verify them by inquiring whether they explain all the facts.

Twelve years ago the Royal Society published a paper by me on the *a priori* analysis of "happenings" including epidemics,[7] and gave me a grant to enable me to acquire the valuable help of Miss Hilda P. Hudson, with whom I continued the paper to a second and third part; but though the paper received the attention of such distinguished mathematical students as M. Greenwood[8] and A. J. Lotka,[6 11 14] few medical writers appear to have noticed it, and some recent books on epidemiology do not mention it. Yet Greenwood said of it when the first part was published:

> "Modern researches fall into two classes. On the one hand those directly or indirectly inspired by the epoch-making discoveries of Professor Karl Pearson in the theory of mathematical statistics; on the other, the independent investigations of Sir Ronald Ross."

I should therefore like an opportunity to recall the attention of the profession to a subject which I hope will ultimately be of considerable service to it.

First, I should say that in 1904 I read a paper at the St. Louis Congress in America on the cognate subject of the random-scatter of individuals, such as men or mosquitos or any other living creatures issuing from a centre outwards in all possible directions. Not being a mathematician I could not solve the problem accurately; but I ascertained that most of the individuals would probably die fairly close to the point from which they started (*British Medical Journal*, May 13th, 1906). The problem was afterwards taken up and accurately solved by Pearson and Blakeman.[2]

A few years later, when writing a report on malaria in Mauritius for the Government of that colony,[3] at a time when few people understood the mosquito theory regarding the carriage of that or of other diseases, I thought it advisable to indicate mathematically how such diseases might increase or diminish with changes in the local numbers of the insects, however caused. My demonstration was rhetorical rather than rigid (Sections 11, 12, and 13), and was made on the theoretical assumptions that those numbers remain constant for the period under survey, and that every person concerned receives about the same number of mosquito bites in a month. Then, if the number of bites is large enough, the proportion of infected persons in a locality will rise; if it is small enough, the number of infected persons will fall; but if it stands at a certain figure, the total number of infected persons should also remain fixed. I called this fixed condition "static malaria."[12]

By assuming certain constants (which have never been properly investigated) I calculated that the proportion of infected persons to the whole population of a locality should remain fixed if the proportion of carrying *Anopheles* to each person is about $\frac{40}{1-m}$ during one month, where m is the proportion of infected persons to the whole population at the beginning of the inquiry. Thus if m is very small to begin with, the number of *Anopheles* may still be up to about 40 per head of the human population during one month without any change taking place. That is, a locality should probably remain almost free of malaria, although there are as many as 40 mosquitos of a suitable malaria-carrying kind during one month to each human individual in the locality. If the number of *Anopheles* rises over about 40 to each human being in the area under consideration, and if there are by chance any suitable cases of malaria at all in the area, introduced by immigration or in transit, then the number of local cases is likely to begin to increase until it reaches a fixed limit depending on the average number of mosquitos per human being. We can form a rough estimate of that fixed limit (if my assumed constants are nearly right) by obtaining the value of m from the equation above—namely,

$$a=\frac{40}{1-m},$$

that is, from

$$m=1-\frac{40}{a}$$

where a denotes the number of *Anopheles* to each person *in the locality during one month*. Thus if $a=40$, $m=0$, as already stated; but if $a=60$, m will probably rise to a limit of 1/3—meaning that one-third of the whole population will ultimately become infected with malaria if the number of *Anopheles* keeps at that figure, other conditions remaining the same. If $a=80$, half the entire population will probably become infected in time; and if a becomes very large, m will nearly equal unity—that is, almost the entire population—as often happens. Of course, m is not supposed to be capable of having negative values, which would be meaningless.

The principal point indicated by this calculation is that a comparatively small rise in the number of *Anopheles* per man, as the rise from 40 to 60 during one whole month, might nevertheless suffice to send up the malaria rate in a locality from zero to about one-third of the whole human population; which would amount to a serious outbreak. A rise from 40 to 80 *Anopheles* per man per month should ultimately increase the malaria rate from zero to half the population—which would constitute a grave epidemic. Yet such variations in the numbers of one kind of mosquito (only) would probably pass quite unnoticed even by educated residents, and also might possibly be masked by an abundance of other kinds which have nothing to do with malaria. It would be difficult or impossible to establish or even to estimate by observation alone any such a law of correlation between the number of the cases and the number of the carriers concerned.

It may be asked how exactly I computed the number 40 mentioned in the equations given above. It is a convenient integer representing the decimal fraction 39.61, which equals $4\times4\times4\times3\times0.2063$. I conjectured that not more than a quarter of any mosquitos present succeed in biting human beings (about half the number of mosquitos are males, which do not bite at all). Only a quarter of these will succeed in biting a second time, as required by the law of mosquito transmission. Only about one-third will live long enough (about one week) to mature the malaria parasites within them; and only about a quarter of the human cases of malaria will contain the sexual forms of the parasites required for mosquito transmission, at any given moment when a mosquito happens to bite. The fraction 0.2063 was, I calculated, the proportion of human cases of malaria which remain infected for a month when half the cases recover every quarter.

These figures may be inaccurate, and probably are so; but the main object of the inquiry is, not to calculate the exact point at which static malaria commences, but to

show that there must be some such point when the new cases exactly balance the recoveries.

Of course, in practice, the number of *Anophcles* and of the bites given by them are sure to vary with rainfall and temperature—that is, with season; but this must be understood to be the case; and the simple equations given do not pretend to contain any more than a first approximation towards the facts. The mathematical method possesses the advantage of showing, not only the elements which contribute to a result, but also how and how much each element does so—a thing which can seldom be expressed in words alone without much circumlocution.

This work, first given in my report on the prevention of malaria in Mauritius,[3] was repeated and improved in Sections 26, 27, 28 (pp. 151–164) of my book[4,5]. The former was examined mathematically by H. Waite (*Biometrica*, vol. vii, No. 4, October, 1910); but his argument contained a flaw which I pointed out to Professor Karl Pearson, though Waite endorsed my work. Section 28 of my book just mentioned leads to a problem of repeated operations (iteration), but I did not solve it until 1918 (see my paper[10]).

A second edition of my book was required early in 1911, and I determined to add a fuller treatment of this mathematical study in a final addendum to the work. This constituted Section 66 of the second edition.[5] This section consists of thirty-five pages, which contain nineteen subheadings and fourteen sub-subheadings. It continued the theme much more exactly, and referred not only to malaria but to similar happenings. The section was called "Theory of Happenings." The problem before me was as follows: Suppose that some kind of event happens in every unit of time to a given proportion of a population, while at the same time the same population is undergoing constant changes due to births, deaths, immigration, and emigration, at one rate for the affected and at another rate for the unaffected, what will be the numbers of the affected and the unaffected portions of the population respectively at the end of the period considered? Also, suppose that some of the affected portion are constantly reverting in unit of time, then again what will be the numbers of the affected and the unaffected groups at the end of a given period covering t units of time?

These problems led to two simultaneous equations in the finite calculus. The equations were solved and integrated by that calculus, and the solutions were examined in detail. As well known, the finite calculus possesses the advantage that the unit of time taken may be large or small. When it is infinitesimal the finite calculus merges into the infinitesimal calculus, as shown in subsection (7, ii) and the following paragraphs. I also dealt with happenings that were repeated in the same individuals, and went on to examine metaxenous (or heteroxenous) diseases—that is, diseases which are common to two kinds of hosts. The rest of the paper deals with many details, and confirms my previous quantitative studies of malaria in the same book, and also gives some calculated constants; then it goes on to deal with the infinitesimal treatment of the subject. The integrations were obtained and are given; but of course I should like to have dealt with the theme even more copiously than I have done. Unfortunately the paper contains many misprints and omissions, and the author himself finds considerable difficulty in understanding parts of it.*

Some years later I thought it advisable to submit the same investigation to the Royal Society in the form of the infinitesimal calculus only. Not being so hard pressed for time, I was able to develop the subject considerably, and to introduce a special section for the kind of happenings which are connected especially with infectious diseases—*namely, happenings which do not fall at a constant rate on a population, but one in which every infected person tends to infect a given number of healthy persons in his turn.* What would be the respective numbers of the affected and the unaffected groups of the population in this case? Here also I was able to solve and to integrate the differential equations in twenty-six pages containing seven subheadings and twenty-five sub-subheadings; but of course both papers require some mathematical knowledge.

* We are preparing corrected "pulls" of Section 66, and will be glad to supply copies on application.

The Royal Society published the paper[7] in full, and was also kind enough to suggest Dr. Hilda P. Hudson as an expert mathematician to help me. Next year we brought out two succeeding parts of the same paper[9] containing twenty-eight pages, six subheadings, and twenty sub-subheadings. Errata for Part I are corrected at the beginning of Part II.

All the equations must of course be examined from many points of view, and, though we could not consider different diseases in detail, we hoped that our paper would enable more precise studies to be made in the future. Unfortunately Dr. Hudson was called away for war work, and we have not touched the subject again until quite recently. We are now beginning to consolidate and summarize our previous studies and to develop them by means of the finite calculus, the infinitesimal calculus, and by the use of integral equations.

I should add that my paper[7] demonstrated that the sick-to-healthy communication of infectious diseases and the exhaustion of susceptible persons were enough to explain the rise and fall of the characteristic bell-shaped curves of most epidemics—a point on which some doubt was being thrown at that time.

My bibliography contains references to several works, some of which have been examined by Lotka, but all of which I have not read at present. They seem to reach their conclusions by dropping various constants, which, of course, always renders equations more simple but diminishes their general applicability, epidemics of many diseases being modified by small factors which are often overlooked.

THE RELATION BETWEEN RECURRENT ALBUMINURIA, CHRONIC NEPHRITIS, AND TOXAEMIA OF PREGNANCY.

BY

G. F. GIBBERD, M.S.LOND., F.R.C.S.ENG.,

OBSTETRIC AND GYNAECOLOGICAL REGISTRAR, GUY'S HOSPITAL.

THE renal disorders associated with pregnancy have been described as "chronic nephritis," in which the renal disease is the primary fault, and "pregnancy toxaemia," in which the renal disease is entirely secondary to the toxaemia, and as a rule no overlapping has been allowed between these two groups. It has generally been assumed that a patient with pregnancy toxaemia recovers her full kidney function soon after the toxaemia ceases—that is, at the termination of pregnancy, and it follows, therefore, that chronic nephritis should not occur as a result of pregnancy toxaemia. It has also generally been stated that there is no special liability for albuminuria to recur with subsequent pregnancies.

The biochemical counterpart of the belief that albuminuria occurring during pregnancy is due either to pre-existing renal disease or to an acute toxaemia in a patient with previously healthy kidneys is evidenced by the continued efforts to find some biochemical test to distinguish the "nephritic" from the "pregnancy toxaemia," and of recent years a very large number of such tests have been put forward.

Clinicians are continually faced with the difficulty of putting cases into one or other of these hard-and-fast classes, and biochemists have consistently admitted the uselessness of their tests in classifying the borderline cases. Is it not possible that the fault lies, not with our clinical observations or chemical tests, but with our arbitrary classification of all cases into "nephritic" and "pregnancy toxaemia" types—two watertight compartments in which no overlapping is allowed? Is it not also possible that the belief that "pregnancy toxaemia" does not give rise to chronic nephritis is also false? Surely we have had sufficient experience of the completely unsatisfactory position to which these beliefs have led us to examine what evidence there may be for changing them.

First with regard to the question of *chronic nephritis* resulting from pregnancy toxaemia. Recently several observers have published series of cases showing that chronic nephritis does sometimes follow as the result of an attack of pregnancy toxaemia. Caldwell and Lyle[1] found the incidence to be 8 per cent. after eclampsia. Gibson[2] found definite evidence of chronic nephritis in 4 out of 14 patients who had had eclampsia some years previously; and of 12 patients who had suffered from "pre-eclamptic toxaemia," chronic nephritis was found subsequently in 2. In all these patients, Gibson points out, there was nothing to suggest any renal disease antedating the toxaemia. He quotes Koblanck, who found that 6.5 per cent. of patients had chronic nephritis as a result of pregnancy toxaemia. Harris[3] found 3 out of 27 eclamptics had chronic nephritis when examined one year after delivery, and the same observer found that 60 per cent. of patients who had suffered from "pre-eclamptic toxaemia" showed definite signs of chronic nephritis when examined one year afterwards. In none of these cases was there any history of renal disease before the pregnancy. James Young[4] has recently given the incidence of chronic nephritis as 3 per cent. following eclampsia, and 8 per cent. *following* "albuminuria."

These series are surely of more value than the unsupported statements that chronic nephritis does not occur, and, in spite of the frequency with which such statements are made, as far as I am aware there is no published series in support of them. It is sometimes argued that the patients who showed signs of chronic nephritis afterwards were really suffering from chronic nephritis before their pregnancy, but in a series which I published recently[5] care was taken to exclude all cases in which there was any suspicion of pre-existing renal disease. In a group of 37 such patients who had albuminuria with their pregnancy, 14 per cent. were found to have undoubted signs of chronic nephritis when examined at long periods after delivery.

We must therefore admit the possibility of chronic nephritis as a result of pregnancy toxaemia, and it follows that because a patient may be found to have chronic nephritis after a pregnancy with albuminuria she was not necessarily suffering from "nephritic" as opposed to "pregnancy toxaemia" during her pregnancy. She may have been suffering from either, or indeed from both.

The question of the frequency with which albuminuria recurs with subsequent pregnancies has also received attention of late, and here again we are forced to modify views that have held sway for a very long time.

James Young[6] has published a series in which 31 per cent. recurred, and if macerated foetus, abortion, or accidental haemorrhage (in the absence of albuminuria) are considered as signs of toxaemia, the incidence of recurrence in his series reached 44 per cent. More recently the same writer[4] has published a larger series with a recurrence rate of 57 per cent. Included in such series may be a certain number of cases of definite chronic nephritis, which will, of course, show a recurrence rate of 100 per cent. In a series of 28 cases which I published[5] recurrent albuminuria was noted in 19. In 21 cases there was every reason to believe that the patients were perfectly healthy before their first pregnancy with albuminuria, and in this group 12 (57 per cent.) had albuminuria with a subsequent pregnancy. All these patients were free from obvious signs of renal disease in the intervals between pregnancies.

As far as I am aware there are no published series in support of the statement so commonly made that albuminuria of pregnancy seldom recurs.

We are therefore justified in modifying two time-honoured misconceptions about pregnancy toxaemia. We must admit, first, that pregnancy toxaemia sometimes causes definite chronic nephritis (probably in something like 10 per cent. of cases); and secondly, that of all patients who suffer from pregnancy toxaemia and who are apparently free from renal disease afterwards, something like 50 per cent. have albuminuria with subsequent pregnancies.

If these clinical facts are admitted, we are in a better position to consider the difficulty which arises when we try to place all cases of albuminuria occurring during pregnancy into one of two pathological groups. That these two groups—*the "nephritic" and the "pregnancy toxaemia"*—exist is very probable, and the evidence for regarding the kidney damage in the latter group as secondary has been admirably stated and defended by James Young. But the difficulty is that we have four clinical types and only two pathological groups to contain them.

The four clinical types are as follows:

1. Patients with chronic nephritis preceding the pregnancy. These patients, of course, continue with signs of renal deficiency after pregnancy. They form the "nephritic" group.
2. Patients presumably healthy before pregnancy who develop albuminuria during pregnancy, but in whom all signs and symptoms of renal disease disappear after delivery, and do not recur with a subsequent pregnancy.
3. Patients presumably healthy before pregnancy who develop albuminuria during pregnancy, and in whom all signs and symptoms of renal disease disappear after delivery, but recur regularly with subsequent pregnancies.
4. Patients presumably healthy before pregnancy who develop albuminuria during pregnancy, but in whom all the signs and symptoms of renal disease persist permanently after delivery. (These patients are really members of the second group, who, as a result of their first pregnancy toxaemia, develop chronic nephritis, and thereafter become members of the first group. It is not therefore necessary to introduce a new pathological class to explain this group of cases.)

It is the cases in the third group that cause so much difficulty in classification, since although they are apparently healthy in the intervals between their pregnancies, yet they fairly consistently show recurrence of the albuminuria with every succeeding pregnancy. If these cases were rare we might explain their occurrence as the result of chance, but when we realize that they form about half of all the cases of albuminuria, it is quite obvious that something more than chance is operating in favour of recurrence.

There is manifestly some difference between those cases in which the albuminuria recurs with succeeding pregnancies, and those in which subsequent pregnancies are quite normal.

James Young has suggested that this difference is due to some unknown factor, some *inherent idiosyncrasy* to pregnancy, in the former group. He suggests that these patients are really (as opposed to "apparently") free from all renal defect in the intervals between pregnancies, and looks upon every attack of albuminuria with pregnancy in such patients as a primary toxaemia. If this is the case it is difficult to explain why many of these patients do not start this sequence of abnormal pregnancies until late in their child-bearing life. If the peculiar fault is inborn, one would not expect a series of albuminuric pregnancies to be preceded by a series of normal pregnancies in any particular patient. In the series which I published[5] it was pointed out that amongst patients with recurrent albuminuria the first abnormal pregnancy occurred after one or more normal pregnancies in 40 per cent. of cases. In many cases, therefore, we have evidence that this tendency to recurrence is not inborn but acquired.

What is the nature of this "predisposition," and how is it acquired?

The first attack of albuminuria, *if the patient is previously healthy*, we must look upon as being due to "pregnancy toxaemia," regarding the kidney damage as purely secondary. If the patient is fortunate this secondary kidney damage recovers completely, and the patient then embarks on a second pregnancy. For this patient to get a second attack of albuminuria she must be extremely unlucky (since the chance of a 3 per cent. risk of toxaemia sufficiently severe to cause symptoms occurring on two occasions is less than one in a thousand). Yet we know that half of the women who apparently recover completely from their first attack of albuminuria with pregnancy actually do have recurrence. Both these types—those who have a recurrence and those who do not—seem to start off in the same way, and in their first albuminuria are indistinguishable from one another. We have seen that the assumption of an inherent idiosyncrasy on the part of one patient causes certain difficulties in explaining recurrent albuminuria occurring after previous normal pregnancies, and, furthermore, since both these types of patient are identical in their behaviour during their first albuminuria, it is difficult to see that one can have an idiosyncrasy that is not shared by the other.

Is it not better to assume that both these patients are previously healthy women—that both have been unfortunate in striking a 3 per cent. chance of "toxaemia"? So far they are identical, but beyond this each runs a different course. In the one the secondary renal disorder *recovers completely*, leaving the patient free to have a perfectly normal pregnancy next time. In the other the renal damage does not clear up completely, but persists in an amount insufficient to cause symptoms until the onset of the next pregnancy. In other words, this acquired predisposition to albuminuria is simply a low-grade renal insufficiency. The disease is an "occult nephritis," demonstrable only by the most delicate test of renal function that we possess, and that test is pregnancy.

Further evidence in support of this standpoint is obtained from the following series of cases, which occurred in the practice of the Guy's Hospital Obstetric Department, and I am indebted to the obstetric surgeons at that hospital for permission to publish these figures.

Fifty-one patients were studied during at least two pregnancies, the first being associated with albuminuria. Of these, four were suffering from chronic nephritis before their first pregnancy with albuminuria, and will not be considered further.

This leaves 47 patients, all of whom were presumably perfectly healthy before their first attack of albuminuria. They were considered healthy on the following grounds: medical history, urine examination, cardio-vascular examination, and occasionally on the results of biochemical tests. No patient was considered healthy unless there was positive evidence of the absence of albuminuria, and of other signs, at the beginning of pregnancy.

Of these 47 patients, signs and symptoms of chronic nephritis persisted for a year or longer after labour in 6 cases—that is, definite chronic nephritis developed in 13 per cent. Amongst these 6 cases the average time between when the albuminuria was first noted and when pregnancy was terminated was nine weeks.

This leaves 41 patients, none of whom showed any signs or symptoms of renal disease in the intervals between successive pregnancies. They have been divided up as follows: Twenty-seven patients in whom the first albuminuric pregnancy was terminated either by induction or spontaneously within three weeks of the time that albuminuria was first noted; albuminuria recurred with the next pregnancy in 11, giving a recurrence rate for this class of 40 per cent. Fourteen patients in whom the first albuminuric pregnancy was terminated either by induction or spontaneously at some time later than three weeks after the albuminuria was first noted; albuminuria recurred with the next pregnancy in 10, giving a recurrence rate for this class of 70 per cent.

In this series it is seen that the duration of the albuminuria with the first abnormal pregnancy was strikingly long in those patients who subsequently developed frank chronic nephritis, and the deduction is that a prolonged toxaemia is more likely to cause permanent damage in a previously healthy kidney than is one that lasts only for a short time. This point was brought out in the series which I previously published where it was shown that the average duration of the albuminuria was greater in those patients who subsequently developed chronic nephritis than in those who did not. It has also been noted in a slightly different way by Harris and by James Young. Both these writers noticed a higher incidence of chronic nephritis following albuminuria without convulsions than following eclampsia, and both accept the explanation that although the "toxaemia" in cases of eclampsia is very severe, it is often only of relatively short duration.

It is by studying the last two classes that we have an insight into the etiology of recurrent albuminuria. All patients in both these classes were healthy before their first albuminuria—all were free from obvious stigmata of renal disease between their pregnancies—yet some were "predisposed" to albuminuria with subsequent pregnancies, while others were not. The important point brought out by these two classes is that it shows that the incidence of this "predisposition" is influenced by the duration of the first "toxaemia."

In other words, the etiology of the "predisposition" to recurrent albuminuria is similar to that of frank chronic nephritis in these cases. This is further evidence that the "predisposition" is in fact merely another term for chronic nephritis. If the predisposition is inherent, or inborn, or independent of the first attack of toxaemia, it is difficult to see how early induction of labour in a first attack can influence the probability of a subsequent attack, yet the figures quoted show that this influence is quite definite.

We can thus regard all first attacks of albuminuria in previously healthy patients as due to a primary toxaemia—any renal insufficiency being purely secondary. Of these such patients one will suffer such marked kidney damage that she will continue to show signs and symptoms of chronic nephritis so long as she lives. Of the remaining nine patients, all of whom are apparently healthy in the intervals between pregnancies, only four have really recovered their kidney function completely. These four subsequently have normal pregnancies. The other five show a recurrence of the albuminuria fairly consistently with all subsequent pregnancies, because although their kidneys are not sufficiently damaged as the result of their first toxaemia to show signs in the ordinary way, yet, when put to the strain of pregnancy, they show signs of insufficiency. They are, in fact, permanently suffering from "occult nephritis."

As an objection to this view James Young suggests that these patients with recurrent albuminuria conform to the "toxaemic" type clinically, rather than to the "nephritic" type. As far as biochemical observations are concerned the same criticism has been used.

My own experience is that these cases conform accurately to neither type; rather have they some things in common with both types. Thus in cases of recurrent albuminuria it is quite common for the foetus to be macerated and for the albuminuria to take a long time to clear up in the puerperium. These characteristics are rather suggestive of a "nephritic" element. On the other hand, such a patient may actually develop eclampsia, which we accept as evidence of "toxaemia." The chemical estimations in the blood and urine are usually indecisive in such cases.

We can only explain all this conflicting evidence—clinical, etiological, and chemical—by assuming that these patients with recurrent albuminuria are really suffering from both "toxaemic" and "nephritic" albuminuria at the same time. The toxaemic element is supplied every time by the pregnancy (and this may be a "normal" pregnancy in the sense that there is not sufficient toxaemia to cause albuminuria in a patient with healthy kidneys), and the "nephritic" element is supplied every time by the occult nephritis which has resulted from the first "toxaemic" pregnancy.

The objection that it is difficult to see how kidney damage that can pass undetected by all our tests of renal function can yet be a serious factor during pregnancy, is merely another example of the unreliability of our renal function tests; and in the face of evidence there can be

no fundamental objection to regarding pregnancy as the most delicate test of renal function that we possess.

The value of this view of the etiology of albuminuria is twofold. In the first place it gives us a working basis for trying to improve our results. If the recurrent albuminuria is really caused by an occult nephritis due to the first toxaemic pregnancy, plus a subliminal toxaemia due to the present pregnancy, it is by paying more attention to the first toxaemia that we may hope to prevent the occult nephritis, and so avoid at least one important factor tending to cause recurrence subsequently. It has been shown that the length of time the initial toxaemia lasts is of considerable importance in the causation of this occult nephritis; but that this is not the whole question is obvious from the fact that, even when it lasts for only three weeks or less, the recurrence rate is still 40 per cent. We must study carefully these initial attacks of toxaemia to try and discover other factors which tend to cause occult nephritis if we hope further to reduce the incidence of recurrent albuminuria. In the second place this view enables us to explain the difficulty that is so frequently encountered of placing certain cases of albuminuria into one of the two pathological groups, either by clinical or by chemical tests. Many cases belong to both groups at the same time, and we should not be surprised, therefore, when we are unable to class a particular case as either "nephritic" or "toxaemic."

A chronic nephritic who becomes pregnant is suffering from albuminuria which is almost entirely "nephritic" in origin, only a very small element being "toxaemic." At the other extreme is the healthy patient who develops albuminuria during pregnancy. She is suffering from "toxaemia" with no primary "nephritic" element. Between these two extremes come all shades of combinations of the two elements, and many of the recurrent albuminurias can be regarded as a fairly equal mixture of the two pathological processes.

CONCLUSIONS.

Toxaemia of pregnancy can be regarded as the cause of all first attacks of pregnancy albuminuria in previously healthy patients. The renal damage in these cases is purely secondary to the toxaemia.

As a result of this toxaemia a certain proportion (about 10 per cent.) develop frank chronic nephritis, and bear the stigmata of this disease, whether or not they become pregnant again.

A further proportion (about 40 per cent.) recover their kidney function completely after delivery, and subsequently have normal pregnancies without albuminuria.

The remainder (about 50 per cent.) recover their kidney function only so far as to be free from signs of renal disease in the intervals between pregnancies. If they subsequently become pregnant they suffer with recurrent albuminuria.

Recurrent albuminuria may be looked upon as due partly to a subliminal pregnancy toxaemia, and partly to a pre-existing occult nephritis caused by the first toxaemic pregnancy.

Pregnancy itself is the most delicate test of renal function that we possess.

If this view is accepted the difficulties of placing certain cases of albuminuria into one of two pathological groups are easily understood. Many cases of albuminuria of pregnancy are due to a mixture of both the "nephritic" and the "toxaemic" elements.

Although the incidence of chronic nephritis and of recurrent albuminuria can be favourably influenced by earlier induction of labour in the first attack of toxaemia, this measure by no means solves all the difficulties. We have still to find out the other important factors in the first attack of toxaemia which tend to produce permanent renal damage.

CAUSES OF SPINAL COMPRESSION.

BY

J. REGINALD BEAL, M.D.Vict., M.R.C.S., L.R.C.P.,

LATE RESIDENT CLINICAL PATHOLOGIST, ROYAL INFIRMARY, MANCHESTER.

THE following four cases of spinal compression seem worthy of record in view of their etiology and symptomatology; thus in the third and fourth cases tuberculosis and syphilis gave rise to the condition—a comparatively infrequent occurrence. The clinical histories of the patients are given below.

CASE I.

A boy, aged 12, first began to complain of weakness of the legs and difficulty in walking in March, 1927. This was followed in April by increasing stiffness of the legs, until he was confined to bed and was unable to walk. The patient had also noticed that for eight months he had been slowly losing the sense of feeling in the legs. The previous medical and family histories were uneventful.

On examination (January 7th, 1928) the patient was found to be quite normal mentally, and no gross abnormality was noticed as affecting the cranial nerves, or the motor or sensory systems in regard to the arms. The lower limbs showed a tendency to involuntary flexion when handled; there was weakness, increase of tone, and very marked loss of power in both legs. The knee and tendo Achillis jerks were markedly exaggerated; the plantar responses were extensor and Oppenheim's reflex was present; the superficial abdominal reflexes were absent; and ankle and patella clonus were present. Sensation to light touch was impaired to the level of the fourth rib, and to a three-inch brush to the level of the umbilicus; heat and cold perception was affected over a similar area. The joint and vibration senses were impaired over the lower limbs. The fundi were normal. No changes were noticed in the other systems.

The Wassermann reactions of the blood and cerebro-spinal fluid were negative, as was also an *x*-ray examination of the spine. The Queckenstedt test showed a complete block, while the fluid removed from the cisterna magna and the lumbar region gave evidence of stasis of the cerebro-spinal fluid when examined chemically.

Lipiodol injected into the cisterna magna came to rest at the level of the second dorsal vertebra, and was crescentic in shape. A laminectomy revealed the presence of an extradural tumour at the level of the third dorsal vertebra. This was removed; the patient made an uneventful recovery, and is now able to walk about in a normal fashion. The tumour on section proved to be an endothelioma.

CASE II.

A woman, aged 53, first began to be ill with a dull aching pain at the lower part of the spine six years ago. Two years ago this pain grew worse, and tended to pass round the lower part of the abdomen, and down the legs to the knees. Six months ago the legs grew weak, and tactile sensation began to diminish. The patient became unable to walk.

On examination on January 24th, 1928, the patient was found to be quite normal mentally; there was no gross abnormality affecting the cranial nerves, and the motor and sensory systems in the arms were not involved. The legs showed loss of power and a slight increase of tone, but no wasting; the knee and tendo Achillis jerks were sluggish, there was no ankle clonus, and the plantar response was extensor on both sides. There was loss of sensation to pain, touch, heat, and cold to the level of the umbilicus. The fundi were normal, and the other systems showed no changes. The blood count was quite normal, and the Wassermann reactions of the blood and the cerebro-spinal fluid were negative. An *x*-ray examination showed some osteo-arthritis of the dorsal spine. The Queckenstedt test revealed a partial block, while examination of the fluid removed from the cisterna magna and lumbar regions gave evidence of stasis.

Lipiodol injected at the cisterna magna came to rest at the level of the eleventh dorsal vertebra. A laminectomy revealed the presence of an intramedullary tumour at the level of the eleventh dorsal vertebra. Removal was impracticable, so the dura was incised to effect a spinal decompression. The patient is now having *x*-ray treatment, and shows slight improvement.

CASE III.

A man, aged 27, first complained in May, 1928, of loss of the use of the right leg, followed in two or three days by loss of the use of the left leg. About fourteen days later the paralysis became complete, with total anaesthesia to the level of the umbilicus. The patient had suffered from Pott's disease since the age of 5.

On examination (June 16th, 1928) he was found to be thin, and to have clubbing of the fingers; the spine showed marked kyphosis and lordosis, but there was no tenderness on pressure on any part. The nervous system showed the following changes. The legs were flaccidly paralysed, with loss of power and tone; the knee and tendo Achillis jerks were just present; the plantar response was extensor on both sides; there was no ankle clonus, and the superficial abdominal reflexes were absent. There was loss of sensation to pin and brush *to eight inches above the umbilicus, with a* tendency to harlequin distribution. No gross changes were noticed in any other system, apart from the deformity of the chest due to the spinal changes.

An *x*-ray examination of the spine showed old Pott's disease, with angular curvature in the mid-dorsal region, as a result of which the thoracic cavity was shortened and distorted. The Wassermann reactions of the blood and cerebro-spinal fluid were negative. The cerebro-spinal fluid taken from the lumbar region showed xanthochromia; the cells numbered 2.3 per c.mm., all being lymphocytes. Protein was present to the amount of 880 mg. per 100 c.cm.; the chloride figure was 720 mg. per 100 c.cm., and the sugar 0.05 per cent. No tubercle bacilli or other organisms were seen.

A laminectomy was performed. This revealed at the level of the fourth to the seventh dorsal vertebrae a reddish-blue, thickened, nodular dura, which enclosed the cord in a collar. The cord was non-pulsatile, and could not be isolated. Some thick, greyish pus exuded from this tissue, and a section of it showed tuberculous granulation tissue. Tubercle bacilli could not be demonstrated in the pus or in the tissue. The patient was discharged unrelieved.

CASE IV.

A man, aged 61, first noticed about eighteen months ago that his right leg was becoming weak. This change slowly developed in the left leg, and four months afterwards stiffness slowly came on; the patient states that his legs tended to jerk up. He added that *six months previously he had a girdle pain at the level of the* umbilicus, and that he was unable to appreciate heat and cold in the legs.

On examination, on April 30th, 1928, the nervous system showed the following changes. The cranial nerves were unaffected, but there was marked wasting of the arms and weakness of the small muscles of the hands, with some slight inco-ordination in the finger-nose tests; the reflexes were sluggish. The trapezius muscles and the sterno-mastoids were very wasted. The legs showed a tendency to a "mass reflex"; the feet exhibited pes cavus, and there was loss of power, marked wasting, and increase of tone. The knee and tendo Achillis jerks were sluggish; there was no ankle clonus; the plantar response was extensor; and Oppenheim's reflex was present. The superficial abdominal reflexes were absent. Sensation to pin and brush was impaired over an area extending from six inches above the nipple and down the inner side of both arms, involving all the fingers, but sparing the thumbs. The Wassermann reaction of the blood was positive in a 1 in 45 dilution, and weakly positive in the case of the cerebro-spinal fluid; this fluid contained 6.6 cells per c.mm.—all lymphocytes; chemical examination of the fluid obtained from the cisterna magna and lumbar regions gave evidence of stasis.

Lipiodol injected at the cisterna magna lodged chiefly in the cervical region. The patient was treated with antisyphilitic measures, but died in about three weeks.

A necropsy revealed the presence of syphilitic aortitis and an extradural cyst at the level of the third to the fifth cervical vertebrae. The cyst was about three-quarters of an inch in diameter, and contained brownish material; the corresponding area of the cord was softened. A section of the cyst showed that it was a gumma undergoing degeneration. The spinal cord below this level showed degeneration due to compression by the cyst.

The points of interest in these cases are the following:

1. In three of the cases (Nos. I, III, and IV) the first abnormality noticed was impairment of the motor system occurring much earlier than sensory involvement.

2. In cases Nos. I and III pain was never reported, while in Case II the pain complained of for six years was probably due to the osteo-arthritis, and only latterly was attributable to the tumour.

3. It is also of interest to note that when pain was complained of it was not felt at the level of the tumour, and was probably due to stretching of the sensory tracts in the cord.

4. Another point of interest was the occurrence of pain in Case II, which was an intramedullary tumour.

I am indebted to Dr. D. E. Core for permission to publish these cases, and to Mr. G. Jefferson for operative details.

CONGENITAL RETROPERITONEAL HERNIA

BY

F. W. SUMNER, M.D., B.CHIR.CAMB., F.R.C.S.ED.,

SURGEON, DORSET COUNTY HOSPITAL, DORCHESTER.

RETROPERITONEAL hernia is an uncommon condition. Moynihan and Dobson have dealt with the various forms and their method of origin in their valuable and exhaustive work *Retroperitoneal Hernia*. The case here described does not conform to any of the types noted therein. It was obviously a congenital hernia, comparable in many ways to a left duodenal hernia as described by them.

A farm labourer, aged 66, had suffered for years from occasional attacks of abdominal discomfort, which he described as "indigestion," and could usually attribute it to certain foods, especially pastry, after the ingestion of which he would get epigastric discomfort, lasting from a few hours to one or two days.

In January, 1921, he was admitted into the Dorset County Hospital with, apparently, symptoms pointing to acute appendicitis; the surgeon's notes state that the appendix was inflamed, and was removed; there is no mention of any other abnormal condition in the abdominal cavity having been noticed.

On January 29th, 1926, at 10 p.m., he was admitted into the same hospital under my care, suffering from intestinal obstruction; he gave the following history. On January 27th he awoke quite fit, had his usual breakfast, enjoyed the usual action of his bowels, went as usual to his work in the fields, returned home for his midday meal, at which he ate peas, returned to his work, got "indigestion," which he attributed to the peas, and was so uncomfortable that he returned home and went to bed. On January 28th, at 2 a.m., he vomited; this relieved him somewhat. His medical attendant saw him and treated him. The discomfort continued; notwithstanding the use of aperients, his bowels did not act. The condition remained the same on the 29th; at 7.30 p.m. he vomited some "brown, nasty-smelling stuff"; he was sent into hospital.

On admission his temperature was 97.5° F., pulse 104, respirations 24; he had little abdominal pain, but was uncomfortable. His face was quite placid, and even cheerful during conversation; his heart and lungs were normal; his abdomen was a little "*en garde*"; although slight, it was quite definitely so; the abdomen was a little prominent, chiefly in the umbilical and hypogastric region; it did not move with respiration; there was no peristaltic movement to be seen or felt, nor was anything to be seen or felt at any of the hernial orifices; the rectum was, on examination, found to be empty, and the prostate was enlarged. An enema was given, and was returned clear.

In spite of his slight symptoms an immediate laparotomy was performed at 11 p.m. He was given ether by the open method. A catheter drew off 20 oz. of normal urine. The abdominal cavity was opened by a left paramedian incision; the edges of the incision were well retracted; no bowel came into view, but a large, flat, tense, elastic swelling, with the great omentum spread over it, was in contact with the anterior abdominal wall. On pushing upwards the great omentum there was exposed to view a large, smooth, shiny sac wall, in which distended coils of intestine could be seen tightly packed. On exploring the lower portion of this it was found to extend into the pelvis, reaching to the level of the promontory of the sacrum. The fingers could be passed behind the sac round its lower convex surface; following the sac upwards anteriorly it was found that the transverse mesocolon was arching over it and deeply indenting it. There was only a small portion of the terminal ileum free in the general peritoneal cavity, and this, together with the caecum and the ascending and descending colons, was collapsed; along the large bowel were small scybala at intervals. Coursing in the front wall of the sac from below upwards, and slightly to the right, were three small long blood vessels. Evidently the whole, or practically the whole, of the small intestines and the mesentery were packed away in the sac.

A hole was made in the front wall of the sac, in a bloodless area, and the intestines popped out; these were not greatly distended, and were only slightly congested. Five different portions of gut, which had evidently been nipped by the transverse mesocolon, acting as a constricting band, showed marks of this pressure in linear chocolate-coloured discolorations; each mark was about an eighth to a quarter of an inch wide, and varied from one to three inches in length; in no case was the viability of the bowel impaired. The constricting mesocolon could now be felt to be quite free from the sac wall, it being possible to sweep the finger under it from one side to the other of the three-inch area. The constricting band having been loosened and the bowel released, the toilet of the wound was completed, and the patient returned to his bed.

On recovering from the anaesthetic he began to complain of increasing pain in his right chest. Notwithstanding appropriate treatment, his breathing became more and more laboured and

quickened; he had crepitations at his right base, and he died in twenty-four hours. A limited *post-mortem* examination only was allowed.

Post-mortem Findings.

The lower lobe of his right lung was found to be in a state of acute congestive engorgement.

Commencing at the ileo-caecal junction the collapsed ileum was traced proximally. A length of 1½ feet of collapsed ileum lay free in the peritoneal cavity between the lower right side of the sac and the collapsed caecum, and then passed through an aperture into the hernial sac; this aperture admitted two fingers, was situated on the right side of the sac, and faced to the right; it was at the level of the third lumbar vertebra; through it passed only this *one piece of bowel. The rest of the small intestine and the* mesentery had been all contained in the sac. The entering piece of bowel into the sac was found to consist of the uppermost part of the jejunum; the duodeno-jejunal flexure had not emerged into the general peritoneal cavity as usual, but had been, or rather its peritoneal covering had been, involved in the upper anterior sac wall; for a distance of two inches it was part of the wall, and then gradually became freer and freer, until it finally emerged free into the interior of the sac. About this level the transverse mesocolon arched horizontally over the sac; a finger could be easily passed under this, between it and the sac wall, and swept from side to side, a distance of three inches; it had a free, rounded, thickish edge; it looked like, and had acted as, a band constricting the sac—*the more distended the sac, the greater the constriction.* The fingers in the sac, passed upwards beyond the level of the duodeno-jejunal flexure (in the wall of the sac), showed that the sac cavity extended upwards behind the pancreas, which, like the duodeno-jejunal flexure, was an integral portion of the anterior sac wall in this region; at the upper margin of the pancreas the sac cavity ended, the peritoneal covering of the posterior surface of the pancreas fusing with that of the posterior abdominal wall. When the hernial sac was removed for preservation as a specimen, the duodenal flexure and a portion of the pancreas had to be removed also. In the developing pancreas, when it is completely covered with peritoneum, and after it has completed its rotation to its final position, the posterior surface of the pancreas, with its peritoneal covering, lies against the posterior abdominal wall covered by its peritoneum; normally these two layers fuse together, and the intervening space is obliterated; in this case, for a distance of three inches across its middle, fusion had only taken place at the upper border, the remaining unobliterated space going to make part of the hernial sac.

Tracing the anterior wall of the sac downwards it extended as low as the promontory of the sacrum, where, after curving round its contents, it passed upwards, lying on the posterior abdominal wall and its covering peritoneum, *until it reached the* mesentery, to which, half an inch from its base of attachment, it was fused in a very definite thickened white line of fusion. The mesentery had a smaller line of attachment than usual; the margins of the sac were spread out on each side to the sides of the spinal column; the inner surface of the sac was smooth and shiny; the posterior abdominal wall, covered by its peritoneum, was the posterior wall of the hernia.

Remarks.

Thus the small intestine with its mesentery was not, as is normally the case, free in the general peritoneal cavity, but was confined in a space at the back of the abdomen. It would appear that through an error in development an adventitious fold of peritoneum extended down from the duodeno-jejunal flexure and became fused below to the peritoneum covering the inferior leaf of the mesentery. The small intestine, mesentery, and posterior abdominal wall had their usual peritoneal covering; this space was a closed cavity, except for the aperture giving exit to the ileum; the duodeno-jejunal flexure, instead of emerging from behind the peritoneum into the general peritoneal cavity, emerged into this compartment. The posterior wall was a fixture, and could not expand, the anterior wall could, and did so, in every direction except at its upper end; but here the pressure of its contained bowel kept open the space between the left central portion of the pancreas and the corresponding portion of the posterior abdominal wall, each being covered with its own layer of peritoneum. These normally fuse together. *In this region, also, the* normal development of the transverse mesocolon was interfered with, it remained in its central portion as a bridge passing over the sac.

For sixty-six years *the small bowel had functioned satis*factorily, enabling the patient to carry on his arduous duties without any great disability; but, finally, an indiscretion in diet had fired the mine and converted the potential *stricture into an actual one, and a vicious circle* was set up between an ever-increasing distension of the sac and an ever-increasing pressure of the bridge.

TWO CASES OF OVARIOTOMY I OVER 70 YEARS OF AG

BY

LESLIE WILLIAMS, M.D., M.S., F

SURGEON TO OUT-PATIENTS, QUEEN CHARLOTTE'S HOSP SAMARITAN HOSPITAL FOR WOMEN; CHIEF ASSISTA OBSTETRIC UNIT, UNIVERSITY COLLEGE HOSPI

OWING to the comparative rarity of the operation of ovariotomy in women over 70 years of age the following two cases which were under my care in the "unit" beds of the new obstetric hospital, University College Hospital, seem worthy of publication. Including the 10 cases published by Dr. H. R. Spencer[1] in 1923, 147 such cases of ovariotomy had been recorded up to that date. Since then the records of the following 8 cases have been found in the literature. For assistance in this search I am indebted to Mr. Malkin, the second assistant on the obstetric unit.

In the following list I have not included the 4 cases of malignant ovarian tumours in women over 70 years of age found among 13,259 cases admitted to the University Hospital, Philadelphia,[2] for it is not stated whether they were operation or *post-mortem* specimens.

Cases found in the Literature since 1923.

Tixier, L., and Pollosson, E.: *Gynécol. et Obstét.*, 1925, tome xi, observation vii. Mme M., aged 73. Right ovariotomy, February, 1924.

Moulonguet-Doléris, P.: *Gynécol. et Obstét.*, 1924, tome ix, observation v. Patient aged 70. Hysterectomy and ovariotomy; serous cyst of left ovary.

Reynes, H.: *Marseille-méd.*, 1924, lxi. Patient aged 74. Laparotomy; recovery.

Koucky, J. D.: *Annals of Surgery*, 1925, lxxxi. Mentions one ovarian dermoid occurring in the decade 70–79.

Pribram, E. E.: *Zeit. f. Geburtsch. u. Gynak*, 1924–25, lxxxviii. Three cases. (1) Frau Th. L., aged 70. Left ovariotomy, 1921. (2) Frau L. W., aged 70. Left ovariotomy, 1920. (3) Patient aged 70. Ovariotomy. (These three cases do not appear in Dr. Spencer's "extra cases.")

Isbruch: *Zentralbl. f. Gynak.*, 1926. Frau L. F., aged 70. Right ovarian dermoid removed together with uterus and left appendages, December, 1923. (This case is also mentioned by R. Mayer: *Zentralbl. f. Gynak.*, 1925.)

The Author's Cases.

CASE I.

E. S., aged 75. A married woman who had had seven children, the last confinement being at 39 years of age, was transferred from the surgical wards of University College Hospital to the New Obstetric Hospital on August 6th, 1926. There had been no miscarriages, and the menopause occurred at 50 years of age.

She complained of constant pain in the lower part of the abdomen for the past week. The pain first began at night, waking her up, and had recently been steadily increasing in severity. Up to five months before admission micturition had been normal, but during the last few months urine had frequently been passed involuntarily in small quantities.

The abdomen was distended, resonant to percussion in the flanks, but dull in the umbilical and hypogastric zones. A tender cystic tumour could be felt *rising out of the pelvis and* reaching to 1½ inches above the umbilicus. No fluid thrill could be obtained.

On vaginal examination it was found that the cervix had been pulled up to a high level, and the pelvis felt empty. The diagnosis of twisted ovarian cyst was made and ovariotomy recommended.

The patient, who was a cheerful and intelligent woman, asked for time to consider if it was "worth it" at her age, and to consult her husband; but the pain increased, and she soon decided to undergo the operation.

On August 10th ovariotomy was performed under chloroform anaesthesia. Some little difficulty was experienced owing to *the friable nature of the pedicle, but the operation was com*pleted in twenty minutes, the cyst being removed intact. Contrary to my usual custom, I used catgut in suturing the abdominal wall (I was trying catgut on a series of cases at that time)—continuous for the peritoneum and three sections of continuous suture for the fascia. The skin was united by clips and an anchored dressing fixed by deep "through-and-through" silkworm-gut sutures.

On he specimen consisted of the left tube and mesosalpinx, together with an ovarian cystadenoma measuring 8 by 9 by 8 inches, which contained 4 pints 10 ounces of dark-coloured fluid. The cyst wall was mostly thin, but in one moderately large area the wall was heavily infiltrated with blood and measured 1 inch in thickness. The remains of broken-down septa could be seen on the inner surface of the cyst, but there were no papillomata.

The microscopic sections are of very little interest, and show chiefly fibrous tissue infiltrated with blood.

The patient made an uninterrupted recovery, the temperature never rising above 99.2°.

Without borrowing too much from the above-mentioned article by Dr. Spencer, it may be of interest that this case is similar in several points to some of those he mentions. Thus he points out that malignancy is rare (4 per cent.); that the cheerful woman who is not too fat is a good subject for operation despite her age; that no time should be wasted at the operation; and that the after-care is very important, for there is a liability to chest complications and mental disturbance in these old women.

CASE II.

J. W., a widow, aged 71, had never been pregnant. She passed through the menopause when 48 years of age. She was first seen in the medical out-patient department because she had had pain in the small of the back for three days. Some five and a *half weeks previously* she had had an attack of diarrhoea lasting for sixteen days. The importance of this symptom will be realized. Usually her bowels were opened regularly.

When the physician made his examination he found a "lump" on rectal examination. I was asked to examine the case, and made the following note: "Sigmoid colon palpable and tender. Uterus rather large for patient's age. In close apposition to its right lateral border is a semi-solid tumour not quite as large as a tennis ball. High up in the posterior fornix is a solid wedge-shaped mass. No evidence of carcinoma of the breast or of the stomach. No ascites. On rectal examination no rectal growth can be felt."

The diagnosis of ovarian cyst—possibly a dermoid—was made and ovariotomy advised.

On August 25th I opened the abdomen and found a right ovarian tumour, the size of an orange, embedded in adhesions. The adhesions were separated and the cyst—which on section proved to be a dermoid—removed. Further exploration revealed the real cause of the trouble. High up in the rectum was a carcinoma. It would have been out of reach to rectal examination, but was probably the "wedge" described in the "present state." Unfortunately the growth was inoperable, as it had become adherent to, and had invaded, an adjacent coil of small intestine. There were no obstructive symptoms and no distension of the bowel. Colostomy was not performed.

The operation took thirty minutes; the abdominal wall being closed as in Case I, except that interrupted sutures were used for the fascia.

The great interest of this case to me is the mistake—by which I hope to profit—which I made in diagnosis. In the first place I suspected that the tumour was a dermoid from the peculiar consistency which one associates with these tumours when examined bimanually. Now I should have realized that it was unlikely that a dermoid would suddenly begin to give trouble at 71 years of age, and I should have paid more attention to the one attack of diarrhoea. Then, although no rectal carcinoma could be reached by the examining finger, the sigmoidoscope might have revealed the real trouble. One other point of interest is that dermoids form less than 2 per cent. of ovarian tumours removed after 70 years of age (Spencer, loc cit.).

The further history of the case is as follows:

Recovery from the operation was fairly satisfactory. The wound healed by first intention, but the patient began to feel abdominal pain some ten days after the operation. Flatulence became a troublesome symptom, her appetite failed, and her general condition deteriorated. Some time afterwards she was admitted to the surgical wards and colostomy was performed.

A NEW DAYLIGHT LAMP FOR ACTINOTHERAPY AND GENERAL ILLUMINATION.

BY

ALBERT EIDINOW, M.B., B.S.LOND., M.R.C.S., L.R.C.P.

THE principal sources of radiation which are employed in actinotherapy are natural sunlight, arc lamps, mercury vapour lamps, and incandescent tungsten filament lamps. Solar radiation, compared with that from any other source of light, has the greatest luminous efficiency. The distribution of the spectral intensity of sunlight is variable, and hitherto no artificial source of light has been comparable to the sun either in relative intensity or in the nature of the rays emitted. The lamp which is described has been designed to produce a balance of visible and ultra-violet rays comparable to that of sunlight in relative intensity of radiation and in biological action.

Solar radiation, as it reaches the earth at sea-level, emits a number of waves of light extending from 2,900 A.U. in the ultra-violet region to 30,000 A.U. in the infra-red *region*. The energy distribution may be summarized as in the following table, which approximately indicates the percentage energy in selected regions of the spectrum.

TABLE I.

Ultra-violet Region:		
2,900-4,500 A.U.	= 12%	= 12% total energy.
Visible Region:		
4,500-5,500 A.U.	= 20%	= 51% total energy.
5,500-6,700 A.U.	= 17%	
6,700-8,000 A.U.	= 14%	
Infra-red Region:		
8,000-14,000 A.U.	= 25%	= 37% total energy.
Over 14,000 A.U.	= 12%	

The absorption of ultra-violet rays by the layer of ozone situated some thirty miles high produces a very rapid fall in the intensity of rays shorter than 3,000 A.U. and limits the solar spectrum under best conditions to *approximately* 2,900 A.U. Coblentz has pointed out that it is difficult to make an exact radiometric comparison between the radiations from the sun and those from other sources of light, because all the sources are at different temperatures and have different types of emission spectra. The experiments carried out by Professor L. Hill have shown that the high intensity of rays from 3,500 to 2,900 A.U. present in sunlight produces biological action and affects the living skin in the same way as the shorter ultra-violet rays of weaker relative intensity emitted by the usual artificial sources of light.

The incandescent tungsten filament gas-filled lamps emit a "continuous band" type of spectrum similar to sunlight, but have a greater relative proportion of red and orange rays, and the *ultra-violet* rays are limited to 3,500 A.U. They are efficient for visible ray therapy, but do not produce erythema action on the normal skin, this effect being mainly due to rays shorter than 3,100 A.U. Mercury vapour lamps made of quartz emit ultra-violet rays as short as 2,200 A.U.; they are of great intensity in the green, blue, and violet portions of the visible spectrum, and 60 per cent. of their total energy is due to ultra-violet rays. The great intensity of erythema-producing rays present restricts the use of these lamps. Dosage must be carefully controlled, and the specialized technique of "short ray" therapy should be employed. A vitreosil screen or a mercury vapour lamp made of frosted vitreosil instead of quartz cuts out all rays shorter than 2,500 A.U. and reduces the intensity of the ultra-violet rays from 3,500 A.U. to 2,500 A.U. to about one-tenth. At a distance of 30 inches the minimal erythema dose is produced by a quartz mercury vapour lamp in three to five minutes; with a frosted vitreosil lamp the same intensity of erythema is produced in forty-five to sixty minutes. The mercury vapour lamp is a cold lamp and does not contain visible red rays or any great intensity of visible heat rays, but by the combination of tungsten filament lamps and the vitreosil mercury vapour lamp a source of light rich in heat, visible, and long ultra-violet rays is produced. The effects produced are similar to the biological action of sunlight.

COMPONENTS OF THE LAMP.

The lamp which has been constructed consists of (1) a frosted vitreosil mercury vapour tube, 4 feet long, of the Hewittic vacuum type; (2) a series of tungsten filament gas-filled lamps of low voltage; (3) a selective glass filter for ultra-violet rays shorter than 2,500 A.U. (See Fig. 1.) The vitreosil mercury vapour tube is automatic in starting; it can be placed in any position, either horizontal or vertical, and it is completely silent. A direct or alternating electric supply of 3.5 to 7 amperes and 150 to 250 volts is necessary, making a kilowatt output of 0.7 to 1.5 approximately. The spectrophotographic examination of the lamp shows that ultra-violet rays up to 2,500 A.U. are emitted. The intensity of radiation from 3,850 A.U. is greatly reduced compared with that emitted by the quartz mercury vapour lamp running at 3.5 amperes. In the visible region of the spectrum the lamp is rich in green, blue, and violet rays, but is almost entirely deficient of red visible light. The tungsten filament lamps are incandescent gas-filled lamps of 12-volt and 48-watt capacity. A number of these lamps are connected in series. Spectroscopic examination of this source of light shows that it is rich in infra-red, red, orange, and yellow rays, and emits ultra-violet rays to 3,300 A.U. The intensity of red and orange visible light is relatively in excess of the blue and violet light present.

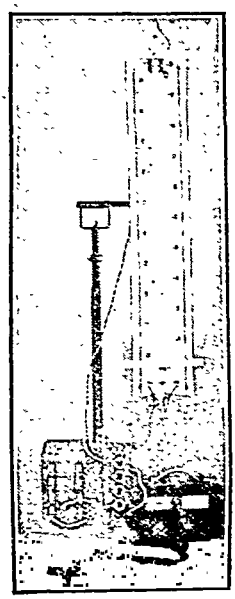

FIG. 1.—New daylight lamp

By the combination of a suitable number of tungsten filament lamps and the vitreosil mercury vapour tube a daylight effect can be produced, by which objects appear to have the same colour as in daylight. The excess of blue and violet rays in the mercury vapour tube is compensated by means of the greater proportion of red and yellow rays emitted by tungsten filament lamps. At a voltage of 210 D.C., eighteen 12-volt and 48-watt tungsten filament lamps connected in series and combined with the vitreosil mercury vapour tube, running at 3.5 amperes, gives a white, comfortably warm, and regularly diffused natural light. The ultra-violet screen is a sheet of glass (sanalux 2 mm. thick) 3 ft. 11 in. by 9 in., which filters off all rays from 2,900 to 2,500 A.U. Photographs taken by means of the rays of this lamp compare favourably with those taken in daylight.

By means of a Griffith's cadmium photo-electric cell T. C. Angus has measured the intensity of ultra-violet rays emitted by this source of light. His observations are recorded in the following table.

TABLE II.

Distance from photo-electric cell to lamps=48 cm. Figures in chart indicate the time in seconds taken to discharge gold-leaf electroscope.

	No Vita Glass Screen.	With Vita Glass Screen =7,200–2,800.
Atmospheric quartz M.V.L. (3.5 amps.) ...	Immediate	27.1
Frosted vitreosil lamp (3.5 amps.)	160.0	1,185.0
New daylight lamp, vitreosil tube and visible light (3.5 amps.). Only 9 in. of lamp tested	29.9	276.0

The results of his experiments indicate (1) that the intensity of ultra-violet rays up to 2,900 A.U. is reduced to one-tenth of that emitted by the quartz mercury vapour lamp, and (2) that the ultra-violet rays from 2,900 to 2,500 A.U. increase the photo-electric effect nine to ten times.

BIOLOGICAL ACTION.

1. *Erythema Production.*—The minimal erythema dose produced by the lamp without the ultra-violet glass screen (using all rays as short as 2,500 A.U.) is 45 to 60 minutes at a distance of 30 inches. With the ultra-violet glass screen it is possible that at 30 inches an erythema could be produced after several hours' exposure.

2. *Action on Infusoria.*—The lethal time for infusoria at a distance of 30 inches was 40 minutes when exposed to unfiltered rays extending to 2,500 A.U., and 120 minutes when exposed through the ultra-violet glass filter to rays extending to 2,900 A.U.

3. *Action on Bacteria.*—A surface culture of staphylococci exposed on a melted agar plate to the source of light was killed in 15 minutes at a distance of 30 inches (rays 7,200 to 2,500 A.U.). Using a sanalux glass screen to filter off rays from 2,900 to 2,500 A.U. lethal action was observed after 150 minutes' exposure. No destruction of bacteria occurred after 2½ hours' exposure through a window-glass screen transmitting rays from 7,200 to 3,300 A.U.

4. *Action on the Haemo-bactericidal Power.*—The hair of the back of a rabbit was removed by means of a depilatory, and the animal was exposed to the rays of the lamp for 2½ hours at a distance of 30 inches. Samples of blood were collected before and after irradiation, and the bactericidal properties of the blood samples before and after irradiation were tested in the usual way. The bactericidal power of the shed defibrinated blood tested *in vitro* had increased after irradiation, in a similar way to the response which occurs after exposure of the skin to sunlight and other artificial sources of ultra-violet rays.

FIG. 2.—Photograph of spectra. 1a, The sun filtered through Br and I screen to show ultra-violet rays. 1b, The sun's spectrum. 2, Quartz mercury vapour lamp. 3, Glass mercury vapour lamp. 4, Incandescent glass tungsten filament lamps. 5, Vitreosil mercury vapour tube and tungsten filament lamps. 6, Vitreosil mercury vapour tube, tungsten filament lamps, and special ultra-violet screen to cut off rays from 2,900 to 2,500 A.U.

SUMMARY.

This lamp affords a useful source of artificial light which can be used for actinotherapy or for general purposes of illumination. Without the sanalux glass filter ultra-violet rays as far as 2,500 A.U. are emitted, which are low in intensity and slowly produce erythema after 45 to 60 minutes' exposure of the normal white skin. Infra-red, visible, and long ultra-violet rays of a constant intensity are transmitted and comfortably warm the body. The total current consumption is 7.5 amperes. The lamp is easily manipulated, requires no attention, and can be tilted to any angle which may be necessary for treatment. It will make an excellent "bed cradle" lamp for treatment of ambulatory cases.

The glass filter cuts off all rays shorter than 2,900 A.U., and the lamp can in this way be utilized as a safe type of artificial light for general use. It is comparable to the solar radiation, and prolonged exposures can be applied

without dangers of injury to the eye or production of rapid erythema. The nature of the light is similar to daylight, and all objects appear in their natural colours. For this reason the lamp should be of practical use in photography and for general purposes of illumination. The spectroscopic examination and the biological investigations which have been described show that this lamp transmits rays of therapeutic value, and is in many respects "artificial sunlight." The lamp is manufactured by the Hewittic Electrical Company, Ltd., Horsham, Surrey.

THE INFLUENCE OF MOVEMENT ON THE TRUNK OF THE HUMAN BODY.

(NOTES ON PHYSIOLOGY AS SHOWN BY A STUDY OF SCOLIOSIS.)

BY

A. MACKENZIE FORBES, M.D., C.M.,

CLINICAL PROFESSOR OF ORTHOPAEDIC SURGERY, MCGILL UNIVERSITY, MONTREAL, CANADA.

In a study of the possible movements of individual vertebrae and the vertebral column as a whole, made prior to 1911, it was found that rotation of the trunk by means of the upper extremities was followed by rotation of the lumbar vertebrae in one direction and of the dorsal vertebrae in the opposite direction. This discovery of an apparent paradox led to an avid study of the influence of movement on the vertebral column. The study was undertaken in the hope that some light might be thrown on the subject of pathological scoliosis. In this brief paper will be shown what has been learned of the physiological in the study of the pathological.

The word "scoliosis" is taken from the Greek, and signifies twisted. It means more. At the time these studies were begun it was felt that there were two types of pathological scoliosis—namely, "functional" scoliosis and organic scoliosis. The first was characterized by lateral deviation of the spine and rotation of individual vertebrae without apparent change in their internal architecture. The second was characterized in addition by distinct bony change.

As years have passed it has become more common to accentuate the fact that scoliosis may be physiological or pathological. Of physiological scoliosis it may be said that the trunk assumes this position many times each day. Physiological scoliosis is due to posture, and in it there is never any change in the architecture of the individual vertebrae. Whenever the trunk is rotated or bent to the side a certain definite roll of the component parts of the trunk takes place. This roll forms a picture which is known as physiological scoliosis, and is the counterpart of pathological scoliosis. Every attitude is either one of strain or non-strain. Thus it is felt that physiological scoliosis may be the forerunner of pathological scoliosis.

The complex picture which is known as scoliosis, when analysed, is shown to be represented by a lateral deviation of the spine, or by lateral deviations of the spine. A posterior prominence of the ribs of one side is also seen—indeed, the rib wall seems often to become crushed in towards the spinal column. It is so flattened that frequently the posterior promiuence becomes razor-like. On the opposite side the thoracic wall is broadened, and there is an anterior protuberance of the ribs. There is, indeed, a flattening of the ribs and a diminution of the thoracic cavity on one side, with a flanging out of the ribs and a corresponding increase of the thoracic cavity on the other side. The spinal column is usually curved in the dorsal region, the curve being convex towards the side on which the ribs are flattened. There are compensatory curves, usually in the cervical and lumbar region. The formation of these compensatory curves may depend on the laws of gravity.

This picture, known as scoliosis, is the same either in physiological scoliosis or in pathological scoliosis, with the difference that from physiological scoliosis, which is due to movement, there is a return to the so-called normal, or passive, position, while from pathological scoliosis there is no return to the normal. In physiological scoliosis there is never change in the architecture of individual vertebrae, whereas in pathological scoliosis change is common.

Many endeavours have been made to use our knowledge of physiological scoliosis in order to treat pathological scoliosis. Superimposing physiological scoliosis of a reverse character on a pathological scoliosis already existing was practised. These endeavours were not successful because pathological scoliosis is always greater than physiological scoliosis, and it is impossible to change the greater by the lesser.

One of the most interesting physiological facts brought out in these studies of scoliosis was that rotation and lateralization (side-bending) both cause scoliosis of exactly the same character. The same picture is seen in either of these movements—indeed, it is impossible to turn the trunk as a whole without the occurrence of a certain definite order of movement of its component parts. It is also impossible to lateralize the trunk, or bend it to the side, without a certain definite order of movement of the individual parts taking place. The turning of the trunk to one side causes exactly the same change as the bending of the trunk to the same side.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

MONILIASIS AND TUBERCULOSIS.

In 1914 a young woman was under my care with chronic bronchitis and asthma, from which she had suffered for several months. She was not doing well, and I sent her to a chest hospital, where her condition was diagnosed as tuberculosis. For domestic reasons, however, she refused to enter an institution, and I was enabled to make a number of careful examinations of her sputum. I did not find tubercle bacilli, but yeast cells were constantly present. Mouth contamination was excluded by the fact that all the sputa I examined were fresh, and from each one I picked out portions from the pellets. Fermentation reactions proved that the yeast cells were maltose, non-saccharose fermenting monilia—in fact, the thrush fungus. After prolonged treatment with alkalis, potassium iodide, and adrenaline, the patient recovered, and has been in good health since. In the case of this patient and other similar cases I did not attach importance to the presence of yeast cells, and assumed some other cause for the bronchial catarrh, until I read some papers by Colonel E. P. Marett of Jersey. In an examination of the sputa of a number of cases of suspected tuberculosis he found that 40 per cent. contained blastomycetes, 40 per cent. blastomycetes and tubercle bacilli, and 20 per cent. tubercle bacilli without blastomycetes. His experience suggested, furthermore, that the first class, if left untreated, soon passed into the second, a damaged lung being particularly susceptible to tuberculous infection, and that the outlook for the second class was less hopeful than for the class of pure tubercle bacillus infection. This latter class, he maintains, should be treated apart from the second in order that double infections might be avoided; the outlook for the second class may be improved by the immediate treatment of the curable blastomycetic infection; and the first class can be cured by means of alkalis, potassium iodide, and blastomycetic vaccines. I think it probable that Colonel Marett has brought to light a truth unsuspected by his predecessors—that chronic blastomycetic bronchial catarrhs occur frequently, and that they are the commonest precursors of tuberculosis in this country. The system of treatment he has devised is within the reach of everybody; its application cannot fail to secure greater efficiency in the treatment of tuberculosis and to diminish the frequency of the disease.

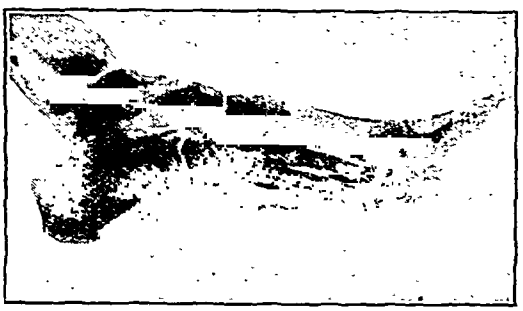
ROBERT CRAIK, M.D.

Ealing, W.13.

KÖHLER'S DISEASE OF THE SECOND METATARSO-PHALANGEAL JOINT.

THE following case is recorded on account of its rarity. Whether the rarity is real or is due to cases being overlooked is uncertain. The clinical condition bears a superficial resemblance to osteo-arthritis, and it is probable that some cases are labelled as such where no *x*-ray examination has been made.

A woman, aged 20, complained of pain and swelling of the second metatarso-phalangeal joint of the left foot. Discomfort in the joint, not amounting to actual pain, was first noticed

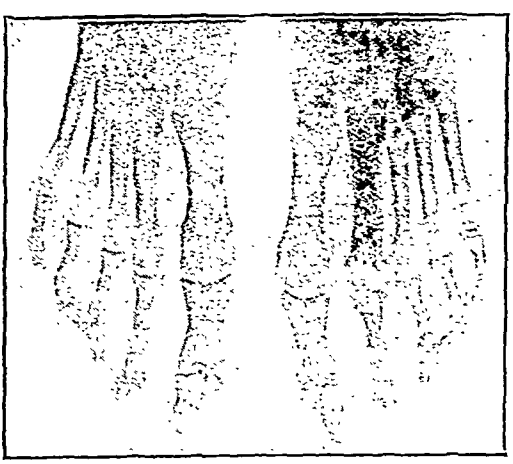


while playing hockey about four years ago, and had been present intermittently since then. During the fortnight before examination the joint had been red and swollen, and walking was distinctly painful.

On examination no crepitus was found, but the head of the metatarsal was felt to be enlarged. There was no limitation of movement. *X*-ray examination revealed the following abnormalities:

1. The whole length of the second metatarsal bone showed marked sclerosis. Its girth was increased by cortical proliferation, but no periostitis was present.
2. The metatarsal head, instead of having a smooth convex outline, was ragged and concave.
3. The base of the first phalanx, instead of having a smooth concave outline, was ragged and convex.
4. The concavity of the metatarsal head was deeper than the convexity of the base of the first phalanx, so that the joint space was widened. The width was slightly greater towards the outer side of the joint.
5. No true osteo-arthritic changes were present.

The disease occurs between the ages of 10 and 18; it is more common in females than in males, and in the right foot than in the left. It may be followed in later life by osteo-arthritic changes.



In regard to etiology, many theories have been advanced, but no settled conclusions are possible at present. Some Continental authors describe an aseptic epiphyseal necrosis with obliteration of the vessels of the periosteum and of the articular capsule. They believe that such changes only result from a series of mechanical insults in which the head of the second metatarsal, owing to its important weight-bearing function, is peculiarly exposed. There is a certain similarity in its radiological appearance with Perthes's disease of the hip-joint. In each case the joint surfaces are irregular, the joint space is widened, and there is increased girth due to new bone formation. Secondary osteo-arthritic changes may occur in both diseases. Whether or not this similarity points to a common etiological factor remains to be proved.

In Köhler's *Röntgenology* will be found a full description and bibliography of the condition.

Reports of Societies.

RETENTION OF URINE.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society, on April 4th, with the president, Mr. GEOFFREY BATE, in the chair, Mr. H. J. MCCURRICH read a paper entitled "Retention of urine."

Mr. McCurrich said that retention of urine, one of the most distressing conditions, might be overlooked, or diagnosed as present when it was really absent. The former error was due to misinterpreting the symptom of overflow due to retention of urine. The second mistake arose from a failure to diagnose suppression of urine; a catheter would clear up the difficulty, and should always be used before a diagnosis of incontinence was made. The lecturer added that he had once seen a patient who had been placed in seclusion as a case of mania. The real trouble was uraemia and retention of urine, due to an enlarged prostate. The man's retention of urine with overflow had been mistaken for incontinence. In partial retention of urine, residual urine remained after micturition, and its amount indicated the degree of obstruction or the weakness of the bladder.

The Historical Aspect.

Retention of urine had occupied the attention of medical practitioners for centuries. Read, in 1588, gave a good description of caruncle, which was the name for stricture; he appeared to consider it a form of new growth, and remarked that Galen used to pluck it forth with iron instruments. He did not dilate the stricture, but passed vegetable stalks through it, and took steps to reduce the congestion. If he could not get a stalk to traverse the stricture he used a lead sound, and, if that failed, a silver or gold one. Wax candles or bougies were used to apply medicaments to the stricture. Ambroise Paré, surgeon to King Henry III of France and Poland, issued in 1579 a work on surgery, which comprised a large range of subjects, including that of retention of urine, or suppression, for these two terms were used synonymously, though Paré stated that in some cases no urine was in the bladder, and therefore a catheter would not help. In the midst of accurate observations, Paré introduced statements that showed that he was a believer in "humours" and in such vital properties of organs as "*attractum*" and "sympathy." He also held the view that seasons affected these matters, and that the best season in which to treat a stricture was the spring. There was no mention of enlargement of the prostate in Paré's writings. Hart, in 1625, in his *Anatomy of Urines*, described the diagnosis of complaints by persons to whom the urine of patients was brought, but whom they had never seen. Hart jeered at them, and asked what would be sent to these persons if retention of urine existed. He gave a disastrous instance of the folly of this procedure. Record, in 1547, in the *Urinal of Physic*, gave various herbal preparations for the treatment of stricture. He mentioned one delightful homœopathic remedy for the treatment of stone which consisted of obtaining a stone passed by a human being, grinding it up with water, and drinking the mixture so prepared. Johann Scultetus, in the *Chirurgorum Armamentarium*, translated by E. B., and published in 1674, quoted from Celsus an excellent account of catheterization. Christopher Brandon Trye of Gloucester, in 1774, had described [illegible] tion at the internal meatus, [illegible]

bladder, and enlargement of the prostate. He described the palliative treatment of an enlarged prostate, a condition which he regarded as invariably fatal, and stated, "It is a melancholy case, but happily does not often occur till that advanced period of life which naturally leads to the grave." He used to inject oil under pressure into the urethra in cases of stricture, through which he could often pass a bougie subsequently. He also invented a vacuum pump with a receptacle for extracting the urine in cases of atony. He mentioned the recent introduction of caoutchouc or flexible gum elastic catheters from Paris. In 1778 Alexander Reid of Chelsea wrote a work called *An Enquiry into the Merits of Operations Used in Obstinate Suppression of Urine.* He advised strongly the method of puncture per rectum practised by Flurant of Lyons. Percival Pott, in 1778, described the reflex retention of urine in such conditions as fistula in ano.

Etiology of Retention.

Mr. McC[illegible] stated that the causes of retention might be [illegible]

Males.

1. Newborn.
   - (*a*) Meatus stuck together by a little dried blood or secretion.
   - (*b*) Pinhole meatus.
   - (*c*) Phimosis.
   - (*d*) Congenital membrane in posterior urethra.
2. Young Adults.
   - (*a*) Acute urethritis, prostatitis, or prostatic abscess.
   - (*b*) Reflex spasm due to inflammation elsewhere—for example, appendicitis, ischio-rectal abscess, etc.
   - (*c*) Trauma locally or to reflex arc.
   - (*d*) Overdistension of bladder.
   - (*e*) Functional or hysterical causes.
   - (*f*) Organic nervous diseases.
   - (*g*) Stone.
3. Middle Life.
   - (*a*) Urethral stricture.
   - (*b*) Tabes dorsalis.
   - (*c*) Causes under 2.
4. Old Age.
   - (*a*) Enlarged prostate.
   - (*b*) Atony.
   - (*c*) Causes under 2 and 3.

Females.

- (*a*) Urethritis.
- (*b*) Retroverted uterus enlarged by fibroids or pregnancy.
- (*c*) Prolapse of urethral mucous membrane.
- (*d*) Caruncle.
- (*e*) Hysteria.
- (*f*) Nervous diseases.

Hamilton Bailey had described the causes of retention according to age, the ages given being those of Shakespeare's seven.

Treatment of Retention.

Mr. McCurrich said that it was a popular but erroneous lay idea that the bladder would burst; actually, if the obstruction occurred at the neck of the bladder, overflow took place after a certain degree of distension. If the obstruction was in the urethra, extravasation and fistulae occurred. Prolonged distension of the bladder led to dilatation of the ureters and pelves of the kidneys, and uraemia. The speaker said that before attempting to examine and relieve a case of retention of urine one ought to have an idea of the history of the case and the probable cause. This was important, because in suspected stricture instruments of small diameter must be used, whereas in enlargement of the prostate it was safer to use large instruments; there was less risk of bleeding from the congested gland with these. Soft rubber and metal instruments were sterilized by boiling; gum elastic and silk web instruments were sterilized by exposure to formalin vapour. Dr. Galt, pathologist to the Royal Sussex County Hospital, had recently tested the efficacy of this method as used in the portable glass tube with a formalin tablet in the perforated container in the cork, and found that this method of sterilization was quite satisfactory. External urethrotomy, apart from puncture for the relief of retention, dated from the early part of the nineteenth century, and in this country was associated with the names of Guthrie and Syme, and later Wheelhouse.

Mr. McCurrich remarked that the disadvantage of Wheelhouse's operation was that great difficulty might be experienced in finding the way through the stricture when the urethra in front of it was opened. He had therefore devised the following operation. The patient was anaesthetized spinally and placed in the lithotomy position. The bladder was opened suprapubically by a small incision, into which a finger was introduced; along this a sound was passed into the internal urinary meatus and through the prostatic urethra. Another sound was passed through the external urinary meatus along the anterior urethra. The tips of the sounds were then only separated by the stricture, and a perineal incision on to the tops of the sounds divided it. The tips of the sounds were exposed; the anterior one was rotated to extrude its tip. Each end of a piece of rubber tubing about the size of a No. 12 catheter was tied on to the sounds, a long window being cut close to the end of the one tied to the posterior sound. The sounds were withdrawn by the way they entered, and the tube was drawn in with them, so that it traversed the urethra and bladder. Each end of the tube was secured by a safety pin, so that however restless and uraemic the patient was there was little risk of his extracting the tube. Each day the tube might be moved to and fro by means of the pin at each end; in this way the urethritis associated with an indwelling catheter was diminished. The tube might be left in for as long as a week. The subsequent treatment and dilatation were the same as for a Wheelhouse operation. Mr. McCurrich had performed this operation first in 1925, and had performed it twice since. The fact that the tube traversed the suprapubic wound did not delay healing.

FUNCTIONAL NERVOUS DISORDERS IN THE SERVICES.

AT the meeting of the Services Section of the Royal Society of Medicine (the new name of the former War Section, *adopted subject to the approval of the Society's* Council) on April 8th a discussion took place on functional nervous disorders in the services. Lieut.-General Sir MATTHEW FELL presided.

Colonel J. C. KENNEDY opened the discussion with some observations on the incidence of hysteria in the army. He said that it was not surprising that many men should have broken down under the strain of their experiences in war, but under normal conditions one was not accustomed to look upon hysteria as a factor of much importance in the male subject. It had, however, gradually been borne in upon him that hysteria did exist to quite an appreciable extent. The incidence was distinctly increasing in the army. In 1927 there were 126 admissions for hysteria, a ratio of 0.7 per 1,000 strength, comparing with a ratio of 0.4 in 1921, and an average ratio of 0.1 for the five years before the great war. Combining with the figures for hysteria those for all diseases of the nervous system, for neurasthenia, for epilepsy, for mental disease, and for disordered action of the heart, it appeared that the incidence of nervous disorders rose in 1921, and although it showed a tendency to fall in subsequent years, it still remained at considerably above the pre-war level. Some idea of the clinical types and etiological factors of hysteria during peace-time conditions was obtained by an analysis of 177 cases made during the eighteen months from January, 1927. In a few cases the diagnosis was uncertain or open to criticism for various reasons. Eliminating these, there were 164 in which the diagnosis of hysteria seemed justified. In 82 of these fits or convulsions were the predominant symptom. The great majority of these patients were admitted to hospital for observation as to the nature of a "fit." Analysis of this group showed evidence of a relationship between incidence and length of service. Of the 82 cases, 32 had had less than one, and 52 less than two years' service. In a group of 10 other cases tremor or spasm was the prominent feature, and again in 19 there were marked paralysis, disturbances of sensation, and aphonia. A considerable

proportion—43—of the total number showed mental symptoms and amnesia, and here again the majority of the cases occurred in the first two or three years of service. Finally, there was a group of 10 cases which had occurred in Aden in association with some cases of neuritis which were at first thought to be beri-beri. The analysis of these 164 cases supported the generally accepted view that the basic factor in the etiology of hysteria was a constitutional or inherent instability of the nervous system. From the service point of view the speaker thought the definition by Osler and McCrae was very apt: "For practical purposes, the physician may think of hysteria as an unconscious mechanism, utilized to protect or remove the individual from a disagreeable, undesirable, or threatening situation." The manner in which these cases were disposed of was recorded in 151 cases: 113 men were returned to duty, and 38 were found unfit for military service. The speaker emphasized that the hysterical condition might be superimposed upon an organic lesion, wound, or toxic condition; hysteria should not be officially diagnosed as such if associated with any organic disorder, as such a diagnosis was unjust to the patient, and created trouble in finally disposing of the case. The decision as to whether the hysterical person should be retained in the service or not depended on a collective consideration of the length of service, the evidence of previous history, and the effect of treatment. Treatment, apart from general considerations of health and the application of electro-therapy, took the form of counter-suggestion or persuasion. A patient not easily amenable to persuasion might require prolonged treatment, and in view of the liability to recurrence, ceased to be an economical proposition for the army under peace-time conditions. At the same time, the principle that no man should be discharged from the service for a curable disability until he was cured, even though he would never make an efficient soldier, was one that the medical authorities would like to see carried out; and, as a matter of fact, the question of specialist psycho-therapeutic treatment had been receiving attention.

Surgeon Rear-Admiral E. T. MEAGHER, R.N., urged that medical officers concerned with the admission of candidates to the service should devote attention to, and make a record of, the mentality of the candidate. Observation should also be made of the recruit during his first year of service to see whether he exhibited any significant behaviour characteristics. In the navy and in seafaring life generally the conditions tended to raise the resistance to hysteria. Hysteria was more frequently exhibited by the less educated classes, and he could not recall having seen a case of pure hysteria in an officer. In the diagnosis of hysteria it was very necessary to make sure that organic disease did not coexist, and the same discretion must be used in neurasthenia. From the naval records there appeared to be little difference in the incidence of the psychoneuroses on comparing the pre-war period with the present; the ratio of psychoneuroses in the navy was 2.6 per 1,000 in 1912 and 2.5 in 1925. The ratio for hysteria, however, had shown some advance, possibly because the medical officer now was more aware of its existence, or because of the increased emotional tendency of the present generation, fostered by the cinema habit and the picture paper.

Squadron Leader M. L. BURTON, R.A.F., said that in peace time the flying branch of the R.A.F. was subject to stresses in excess of those incurred by the other services, and therefore the question of whether an officer possessed a stable and flexible nervous control became of more importance. There had been a more or less steady decrease in the psychoneuroses in the service since 1921. Among the officers, during the past three years, a very much higher percentage of cases had occurred in those who, for various reasons, were not called upon to undertake flying duties. This was explained by the fact that many of these officers had previously been engaged on full flying duty, that they were often older men with heavy responsibilities, and were more likely than the very young men to have intercurrent domestic and private worry, and that in the case of many of them the preliminary medical examination had been less strict than for those intended for the flying branch. In the assessment of candidates for the flying branch account was taken, first, of the personal history, with special reference to any nervous symptom; secondly, of the family history, as to the incidence of any nervous or mental trouble; thirdly, as to the constitutional mental make-up of the candidate, based upon his demeanour during examination and his proficiency in occupations and sports; and, finally, in the absence of any more effective tests, of the results of certain physical examinations, such as the behaviour of the respiratory and cardio-vascular centres under stress, the systolic and diastolic pressures, the pulse, and the deep reflexes as indicating muscular control. As regards the efficiency of these tests, the speaker said that it was significant that a very small proportion of officers in the flying branch broke down, even under conditions of severe stress. With regard to treatment, only selected cases of psychoneurosis of emotional origin could be treated successfully in the service, owing to the time involved. Cases might be patched up, but were liable to recurrence under strain. The speaker pleaded for a common nomenclature for use in the services.

Dr. ALDREN TURNER, speaking as a member of the War Office Medical Board, said that from the cases which came before the Board it was difficult to obtain a trustworthy idea of the incidence of functional nervous disease; for although the patients were numerous, they were usually of a special character, and were brought before the Board for a particular purpose. He thought, however, that hysteria, as illustrated by the usual stigmata of paralyses and fits, was rare. Many conditions upon the borderline of the psychoneuroses might be correctly placed among the minor psychoses and anxiety conditions. There had been opportunities of seeing in young officers cases of fits certified as epileptic developing in special circumstances of mental strain and overwork, and probably to some extent aggravated by personal habits or climatic conditions. Seizures which owed something to this last cause might cease when the officer returned home from abroad. The question arose whether these cases should be placed in the same category as continuing epilepsy, or whether they did not belong to a special class of epilepsy having a psychogenic origin, and should be treated as a temporary disability. The existence of such a group of epilepsies could not be disregarded. In civil practice it had to be recognized that patients exhibited seizures clinically indistinguishable from ordinary epilepsy, as reactions to situations of a purely psychical nature. Many such cases might result from an inability to adjust to special or unusual conditions, and indicated an instability in the mental and nervous make-up. He subdivided into three groups the outstanding functional nervous disorders observed amongst officers as neurasthenia: (1) purely debilitated or nervously exhausted cases; (2) cases showing evidence of anxiety, accompanied by characteristic physical signs; (3) the post-concussional syndrome. There was no definite dividing line, but if the origin of the nervous breakdown were inquired into, evidence permitting of some such subdivision would probably be forthcoming. Reference had been made to a considerable increase of functional nervous disorder, particularly neurasthenia, in the army from 1921. It was difficult to dissociate this fact from the strain of war service, with consequent weakening of nervous and mental resistance. Experience at the Board had proved that a number of officers who in 1914–18 suffered from some temporary form of functional breakdown had a predisposition to relapse under any special strain, such as an infection, a trauma, or even ordinary service peace-time risks.

Sir MATTHEW FELL said that as an administrative officer he was very glad that this subject had been ventilated. It was one of the most difficult to deal with, whether from the point of view of recruiting, invalidity, or attributability. He was prepared to take up the question of inter-service terminology. The Army adhered to the last edition (1918) of the *Nomenclature of Diseases* of the Royal College of Physicians, in which classification there was nothing intermediate between hysteria and psychasthenia, so that, as Colonel Kennedy had said, it was difficult to place the psychoneuroses. If the R.A.F. could produce graduations which were not printed in the nomenclature there was no reason why the army should not accept them.

A MATERNITY SERVICE.

AT a meeting of the Edinburgh Obstetrical Society held on March 15th, with the president, Dr. HAIG FERGUSON, in the chair, Dr. JAMES YOUNG read a paper on "A scheme of maternity service co-ordinating ante-natal, domiciliary, and hospital treatment."

Dr. Young said it was now generally agreed that the high maternal mortality and morbidity rates were dependent primarily on the inadequacy of the machinery of present-day midwifery. The present medical service was wasteful of lives and health because the duties of general practice were incompatible with satisfactory midwifery. The annual death rate among mothers in England and Wales was about 5 per 1,000 live births. This implied the deaths of about 3,000 women every year, and, on a moderate estimate, at least 30,000 more women annually suffered more or less lasting damage from child-bearing and childbirth. The best possible results were found where the service was conducted by midwives with doctors available for the emergencies. The proved advantages of such a combination were seen in the practice of the Queen Victoria Jubilee Institute nurses in England and Wales and in the outdoor practice of the large maternity hospitals, where the death rate was very low. An ideal practice in these regards was the East End Maternity Hospital in London, where for many years the death rate in a total of about 2,000 unselected cases treated annually was under 1 in 1,000—that is, about one-fifth of that obtaining over the rest of the community. On analysis the low death rate in these hospital practices was found in the fact that they were managed by self-contained units each serving its own district in which the normal cases were conducted physiologically by midwives and in which the ante-natal supervision and the management of the abnormal cases were dealt with by the doctors belonging to the service. In this way there was a continuity of supervision and control of the ante-natal, the domiciliary, and the hospital treatment of the patients, and of the personnel responsible for the services. The system made for a physiological management of the 90 per cent. or thereby of normal cases, and for an early discovery and efficient treatment of abnormalities.

Dr. Young believed that an adequate maternity service was possible only if planned on a national basis, having as its object a co-ordination of the activities of the midwife, the doctor, the national health insurance, and the local authorities, which at present were unrelated and often overlapped. This service should work in conjunction with voluntary agencies, such as hospitals, and should include (1) a midwife for every labouring woman, (2) ante-natal supervision in every case, (3) a medical service for complications, and (4) the hospital. Pending a national service much might be done if local authorities undertook to make provision for their own needs. It was important to relieve doctors in busy general practice of the duties of midwifery, and the doctor personnel of the service should consist largely of general practitioners selected because of their special experience and training and of a comparatively small number of specialists. Dr. Young thought that in every area the "unit" system should be aimed at as far as possible, for, by ensuring continuity of treatment and responsibility, it would lead reciprocally, on the one hand, to an elevation of the standard of domiciliary practice, and, on the other, to prevention of the tragedies of the present-day maternity hospitals. The fact that all cases were under the control of the unit from the beginning meant that there was no vitiation of the hospital environment by the introduction of women with passages infected before admission by the injudicious management of some outside attendant over whose methods the hospital had no control. In this way the atmosphere of the hospital was kept secure for clean midwifery. In the East End Maternity Hospital in London, whose practice was based on this system, sepsis had been practically eliminated for many years. On the other hand, infection of the normal case was one of the outstanding disadvantages of the present-day maternity hospitals, which opened their doors to clean and unclean alike. The recent report of the Scottish Board of Health on Maternal Mortality referred to the high death rate in maternity institutions in Aberdeen due to this contagion, and other writers—for example, Janet Campbell—had commented on the same thing. In the Edinburgh Royal Maternity Hospital there had been 72 cases of puerperal sepsis with 5 deaths amongst normal spontaneous deliveries in four years. Dr. Young referred to the complexity of the segregation problems which faced every such mixed hospital, and raised the question whether, under the present unsatisfactory conditions of maternity practice, it might not be desirable to abolish the large mixed hospital and, in such districts, to have two kinds of hospital, the one for "booked" and clean cases—that is, those under the supervision of the hospital—and the other for the infected or suspect cases. Dr. Young believed that the "suspect" cases (for example, the unsuccessful forceps case, the case of placenta praevia plugged before admission, and abortions) raised even greater segregation difficulties than the frankly septic case, and that the tragedies of the hospital sprang chiefly from it.

Dr. E. FARQUHAR MURRAY (Newcastle) read a complementary paper on "The future of obstetrics, with special reference to the development of a maternity service," which is printed this week at page 691.

LUMBAR SYMPATHECTOMY.

A MEETING of the Section of Anatomy and Physiology of the Royal Academy of Medicine in Ireland was held on March 8th, with the president, Dr. W. FEARON, in the chair. Professor T. H. MILROY read a paper on the effects of lumbar sympathectomy on skeletal muscle and on cutaneous vascular adjustments.

Professor Milroy, describing experimental work, stated that the left lumbar sympathetic cord, between the vertebral column and the median border of the psoas muscle, in the dog was exposed in the usual way by the retroperitoneal route. The large ganglion behind the diaphragm was lifted up, a section made just above, and the cord freed from before backwards by clean section (without stretching) of the rami. The cord was then divided below the last lumbar ganglion and removed. The cutaneous vascular changes could be easily followed by observing the surface temperature changes in the cushion pad of the foot by the use of very small surface copper constant and thermo-couples. The couples, opposing one another, applied to the cushion pads of the two feet, and any difference in the surface temperature was noted before the experiment. This examination was made some days before the operation under different conditions of environmental temperature and exercise. During the operation any temperature changes could be readily detected—for example, those produced by the handling and initial section, and those which occurred subsequent to the operation. A slight fall in temperature followed the initial section, but this was succeeded by a gradual slow rise in temperature in the pad on the side of the incision. The higher temperature on the operated side was observable for very long periods after the operation, unless both pads had been cooled down greatly by exposure to cold. Even when there was no temperature difference between the two sides on any particular occasion, the absence of the normal cutaneous vascular adjustments on the side deprived of sympathetic control could be readily detected in the following way. If the hind leg on the operated side was warmed up to 35° C. for three minutes, the warm dry coverings were then removed, and both limbs were exposed to the room temperature (8°-12° C.) in a basement, the pad temperature on the warmed operated side remained much higher than on the other side for at least six minutes, and frequently for a quarter of an hour. When the normal limb was tested in the same way the surface temperature of the warm pad rapidly fell, so that within less than a minute it was normal or subnormal. Subsequently a slight rise in temperature, due to increased blood flow, was observable. The lack of vascular adjustment on the operated side had been quite distinct for three months after the operation, and in the case of a boy, in whom lumbar sympathectomy had been performed two years previously for spastic paralysis, the delay in adjustment was just as evident. Changes in skeletal muscle tone on the sympathectomized side were much more difficult to detect; no difference in gait on the two sides could be detected.

There was the same resistance to bending, and also approximately the same firmness of muscles of the two sides. When, however, the dog was kept lying quietly on its back with the hind limbs gently supported, there was frequently observed, on carefully withdrawing the support, less evidence of a locking tonus during the fall in the sympathectomized than in the normal animal. Testing by Lapicque's method, the chronaxie values were approximately the same on the two sides for the same muscle. The tone of the muscles on the sympathectomized side could be as readily raised by strychnine as on the normal side. As regards chemical changes, so far as the main components which play a part in the contractile mechanism were concerned, no distinct difference could be made out between the muscles of the two sides. The water, glycogen, pyrophosphate, and hexose-phosphate percentages were approximately the same when identical muscles of the two sides were compared. Lactic acid production occurred in the same way and to the same degree on the two sides. As a rule the phosphocreatine (phosphagen) in the operated side musculature was slightly lower and the reaction more alkaline.

Urea Equilibrium in the Kidney.

Professor J. M. O'CONNOR read a communication on the demonstration of a urea equilibrium in the kidney, on behalf of Dr. E. J. Conway, Mr. Moriarty, and himself. It was shown that a theory of the secretion of urine put forward by one of the authors involved a reabsorption of urea from the kidney into the blood, if the concentration in the blood of another substance excreted by the kidney was considerably increased. A trial arrangement for the purposes of the experiment was described, and tests and controls were reported, which showed that on an increase in the sulphate concentration of the blood, urea was taken up by the blood from the kidney.

TORSION OF THE GALL-BLADDER.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, on March 22nd, with Mr. R. A. STONEY in the chair, Mr. H. MEADE showed a case of torsion of the gall-bladder.

Mr. Meade said he had only been able to discover twenty-three cases of this condition in the literature. The clinical details in his case were as follows.

On October 26th, 1928, he had been called by Dr. H. Byrne in consultation to see a woman, aged 36, with an "acute abdomen." She had had no previous illness of any kind. On the day before he saw her she had had an attack of severe pain in the right hypochondrium while at lunch. It was so intense that she sent for Dr. Byrne, but when he arrived the pain had passed away. He examined her, with negative results; the abdomen was perfectly soft, and was not tender. There was a return of the pain the same night, but it had shifted down into the lower abdomen. When Dr. Byrne arrived the pain had again vanished, and the findings were negative. She was free from pain during the rest of the night, but in the morning the pain recurred in the right lower quadrant of the abdomen. When Dr. Byrne examined her for the third time he found that the abdomen was rigid and tender, especially over the appendicular region; the patient's temperature was normal, and her pulse 80.

Mr. Meade saw her three hours later. She was somewhat flushed in appearance, and had a temperature of 99° F. and pulse 100. Her heart and lungs were normal. The abdomen was not distended, but it did not move with respiration; on palpation it was rigid everywhere, but most markedly over the appendicular region, where she complained of the pain. Pressure over the descending colon caused acute pain, referred to the appendicular region. She was passing flatus, and was not constipated. The diagnosis of acute appendicitis was made, and she was transferred to St. Vincent's Hospital, Dublin, where Mr. Meade operated on her that evening.

A McBurney muscle-splitting incision was used, and on opening the peritoneum some brownish fluid escaped, similar to the fluid occurring with an ovarian tumour with a twisted pedicle. Both the appendix and caecum showed signs of peritonitis, but as the symptoms were more acute than the condition showed, and on account of the brownish fluid, the abdomen was opened again in the mid-line. The pelvis was found to be normal, with the exception of about four ounces of brownish fluid. The incision was enlarged, and the gall-bladder was seen to be moderately distended; it was soft to the touch, but as black as ink owing to its being rotated three times on the cystic duct, from right to left. The gall-bladder was gangrenous, including the beginning of the cystic duct. The mesentery, which was about one inch long, was clamped and divided. Mr. Meade then clamped the cystic duct, removed the gall-bladder, and tied the duct and the mesentery. He excised the appendix, fixed the caecum, and closed the abdomen, placing a drain through the first incision up to the liver. The patient made an uninterrupted recovery.

The PRESIDENT stated that he had never come across a case similar to the one described by Mr. Meade, and did not remember ever having noticed, either on the operating table or in the dissecting room, a gall-bladder with a torsion of this kind. He thought that as a general rule diagnosis would be impossible. Mr. H. STOKES said he had seen cases in which there had been two or three torsions before the actual obstruction occurred.

MILK MIXTURES IN INFANT FEEDING.

AT a meeting of the London Jewish Hospital Medical Society, on March 14th, Dr. BERNARD MYERS read a paper on infant feeding.

Dr. Myers said that general experience strongly favoured breast-feeding; should this source diminish, and the usual methods of stimulation of breasts fail to produce sufficient supply, the best plan was to give supplementary feeds of a milk mixture after each breast feed. When, however, the mother's milk secretion had almost ceased, and more especially if it worried her, it was better to give a milk mixture at once if a suitable wet-nurse was not obtainable. The milk mixture that the speaker favoured consisted of certified milk, water, and lactose, and never had any cream added; the omission of cream was due to the fact that the fat and protein of cow's milk was never quite so digestible as that of human milk. He believed in giving 1.5 per cent., and, later, 2.5 or 3 per cent., of fat in a milk mixture, but never more, lest dyspepsia should result. He never advised boiling or even pasteurizing a certified milk mixture, since it should be absolutely safe with ordinary precautions, and did not risk the spoiling of the vitamins. If certified or Grade A milk was not obtainable, it was safer to have the milk just boiled, and to allow it to cool very quickly. When the milk could not be digested, and curds formed in the stools, citrate of soda placed in each bottle was most useful. When the milk supply was not satisfactory it was better to use a good dried milk, of which there were many brands on the market. Condensed milk as a routine was unsatisfactory, though the speaker said he had used it in several cases of premature twins for a few weeks only with good results. In his opinion it was a good plan to give all babies, but especially partly or wholly weaned ones, malt and cod-liver oil from the sixth week onwards, and orange juice night and morning. Protein milk, and also lactic acid milk, had their uses in dealing with fermentation troubles in the intestine, but he did not think it a good plan to use these foods for too long. Some babies who had hypersecretion of the gastric juice did well with small doses of sodium bicarbonate after each bottle, or added to the last part of it. Dr. Myers thought that the proper time to wean breast-fed babies was 9 months, since the only cases of rickets in babies so fed that he had seen occurred in children which had been suckled for more than a year. If a baby gained from four to eight ounces weekly, took sufficient food and digested it; if it had one to three healthy motions daily, slept well, and developed normally; if it had a healthy skin and good general nutrition—the baby was all right, and there was no need to worry. If illness supervened the nutrition soon suffered.

Sterility.

Dr. M. MARCUS contributed some observations on sterility as seen in general practice. He placed the cases of sterility seen by the general practitioner in four groups: (1) those with no abnormality; (2) those with irregular menstruation; (3) those with some pelvic abnormality; and (4) those with obesity or some endocrine disorder. He cited a number of cases in each group, and showed how frequently women were treated at different hospitals by operation and other means, without the husband having been examined. In many cases the sterility was due to the male, sometimes from previous disease, such as gonorrhoea, at other times from no known cause—idiopathic azoöspermia. Dr. Marcus described the various methods of obtaining specimens of the semen, including puncture of the testicle, and indicated the precautions necessary for preserving the specimens for microscopical examination. He stressed the importance of occasionally imparting instruction to patients on the physiology of marriage, and the need for facilities, in connexion with hospital gynaecological departments, for the investigation and treatment of male sterility.

Reviews.

PRINCIPLES OF CLINICAL PATHOLOGY IN PRACTICE.

CLINICIANS may be roughly divided into two groups according to their attitude to the pathologist; there are those who would confine him to his laboratory and only suffer him to issue reports therefrom, and there are those who would entice him to the bedside and encourage him to assist in the elucidation of the problems that arise there. Dr. BOURNE and Dr. STONE belong apparently to the first group, but, realizing that it is nowadays impossible for the practitioner to assess for himself the value of many special investigations, they have, in *The Principles of Clinical Pathology in Practice*,[1] put out a guide which shall enable all to know when and why laboratory investigations should be undertaken and what the answers mean. Whether bottled fruit is really the equal of the ripe fruit off the tree is a question each must decide for himself; but all will agree that it is often a very welcome and perhaps sometimes an indispensable substitute; and there is certainly room for a book that deals with laboratory investigations, as this one does, primarily from the clinical point of view.

The book is divided into eight parts, each dealing with one group of disease or one system—for example, specific infections, blood diseases, gastro-intestinal system; and these parts are subdivided into chapters dealing with individual diseases or organs. Each subject is introduced with a paragraph headed "general considerations," which gives a short account of the general pathology of the disease on which the laboratory investigations are based; these are then enumerated and the information they give is explained. The authors' task is no easy one, for laboratory investigations do not lend themselves readily to an answer of "yes" or "no" in their clinical interpretation; they merely provide facts that have to be fitted in with other facts elicited by other methods. To get over this difficulty the authors have included a good deal of clinical detail that is not ordinarily found in books on clinical pathology, and they have thereby achieved a considerable amount of success. As is inevitable under conditions which demand some degree of precision, there is a good deal of bare statement that will by no means meet with universal agreement from pathologists; but on the whole the general reader probably gains from being left undisturbed by an insistence on the rather numerous exceptions which, though they may be held to prove the rule, cannot be conveniently fitted into the authors' scheme. The general usefulness of the advice on therapeutics is more open to doubt. The art of specific therapy is rather too delicate for the bottling process, and it is probable that anyone who is not himself experienced in it had better apply at first to someone else who is. For example, to say that though specific therapy in erysipelas is generally considered to have little influence on the course of the disease, it is probably wise to use it if specific therapy is to do any good at all each case must be dealt with according to the individual conditions, and though it may be successfully treated with stock vaccine it cannot possibly be treated with stock advice.

The last chapter deals in an attractive and stimulating way with allergy and allergic diseases. This is not really clinical pathology at all, but nevertheless it forms a fitting conclusion to a book that will provide many clinical workers with much information they would otherwise find it hard to come by. An appendix gives some useful notes about the collection of specimens; it would be well to add that the wisest plan of all is to communicate first with the pathologist and ask how he likes it done. Two things we hope to see altered, for widely different reasons, in another edition. The recognition of the *Bacillus anthracis* in the vesicles of an anthrax pustule is certainly *not* a procedure that requires a properly equipped laboratory; a slide, a bottle of stain, and a microscope are all the apparatus required, and to wait for more is to lose time that may make the difference between life and death. In former days we used to talk in plain English of "cutting a section," modern fashion speaks of a "biopsy"; the authors' phrase "biopsical examination" is an ugly tautology that should not be allowed to survive.

[1] *The Principles of Clinical Pathology in Practice.* By Geoffrey Bourne, M.D.Lond., M.R.C.P., and Kenneth Stone, M.D.Oxon., M.R.C.P. Oxford Medical Publications. London: Milford, Oxford University Press. 1929. (Demy 8vo, pp. x + 392; 10 figures. 10s. net.)

THE FUEL OF LIFE.

THIS has been called the Mechanical Age. Certainly there is an inclination to assess the progress of man by his ability to invent machines to carry on his struggle for existence. We feel at home with engines. The vocabulary of mechanics and dynamics creeps easily into our general conversation. There is no more certain way of persuading the man in the street—or, should we rather write, the man in his car?—to take an objective interest in his own body than by inciting him to compare its parts and their functions with those, say, of an internal combustion engine. In *The Fuel of Life*,[2] therefore, Professor J. J. R. MACLEOD has chosen a title which will at once attract interest and convey a definite meaning. A generation which displays greater concern for the fluctuations of the petrol market than for the price of bread may be expected to have definite ideas about the properties of fuel. Lest these reflections might mislead the reader, we should hasten to add that Professor Macleod's book is not a popular exposition of physiology written in the form of a topical allegory. Rather is it a learned and critical discussion of a restricted metabolic problem which invites the serious consideration of the author's colleagues in physiology. At the same time the title conveys its general appeal with intent. Professor Macleod has developed his argument with a simplicity and clarity of description which seeks to make it understandable not only to the academic physiologist, but to that larger audience whose concern is with the practical application of the principles of physiology to the care and repair of health.

The author is not, as a matter of fact, concerned with the mechanics of the animal machine, but with the special problem of the chemical nature of the fuel which yields the energy for vital activities. In the plant it is generally agreed that the three chief nutrient materials—protein, carbohydrate, and fat—are freely converted into one another. In the animal economy, on the other hand, a body of evidence has accumulated in favour of the view that fat is not converted into carbohydrate, although, of course, the reverse process is a fact of universal experience. Since both fat and carbohydrate are undeniable sources of energy, it follows that these two materials must follow independent metabolic routes. How decided has this opinion become is witnessed by the words of Graham Lusk, that great student of nutrition, who has written "one by one the bulwarks of the doctrine of the conversion of fat into glucose have been shattered, and it may now be relegated to the realm of scientific superstition."

Professor Macleod brings the whole subject under renewed scrutiny. As a result he concludes that the defences have, in fact, withstood the assaults rather well. Indeed, he is persuaded that the attack has served only to betray the inherent weakness of the attackers' position. He urges that much of the experimental evidence upon which has been built the case against the conversion of carbohydrate into fat does, when re-interpreted in the light of modern knowledge of metabolism, actually establish the thesis that glycogen must arise from fat under a variety of conditions. This argument involves a review of much of the author's own laboratory, upon such subjects as the work, together with many recent contributions, chiefly from respiratory exchange in starvation, in spontaneous and in experimental pancreatic diabetes, the changes in metabolism under the influence of insulin, adrenaline, and phloridzin, and in isolated tissues. In particular, Professor Macleod insists upon the fallacy of the prevalent assumption that the tissues of a diabetic animal are unable to metabolize sugar. This assumption is entirely without direct proof. A final chapter discusses the possible positions of

[2] *The Fuel of Life.* By John James Rickard Macleod, M.B., LL.D., D.Sc., F.R.S. Princeton: Princeton University Press; London: Milford, Oxford University Press. 1928. (Med. 8vo, pp. ix + 147; 12 tables. 11s. 6d. net.)

acetaldehyde, dihydroxyacetone, and other hypothetical substances of unknown structure in the catabolic path of carbohydrate.

It is not for the reviewer to sit in judgement upon the evidence in the case, even were his verdict to have the weight of authority. Sufficient is it to affirm that the argument has been conducted with discretion, power, and a wide knowledge of the problem.

SINUS THROMBOPHLEBITIS.

GENERAL sepsis originating in suppurative disease of the middle ear is one of the most important complications of otitis media. It is especially so because of its frequency and the difficulty of diagnosis, and because the appropriate treatment can in many cases avert a fatal issue with complete restoration to health. Its importance, therefore, justifies the lordly volume entitled *Sinus Thrombophlebitis*,[3] in which Dr. ALFRED BRAUN of New York has given a complete account of the subject. The actual principles of surgical treatment in the established condition have not perhaps made any fundamental advance since the late eighties; but in knowledge of its pathology, and in the clinical studies which have shown the way to its early diagnosis, there has been great progress; and, as effective treatment is closely dependent on these, the surgery of this condition has thus advanced *pari passu* with pathology and diagnosis. A large part of the book is devoted to the development and anatomy of the venous sinuses. This contains many important points of surgical anatomy, which escape attention in ordinary anatomical textbooks, or at any rate their importance is not emphasized. Anatomical connexions and variations here play an essential part in the pathological conditions when disease occurs, and this aspect receives proper notice. Of the chapters relating to pathology, symptoms, and diagnosis, and finally to treatment, it is only necessary to say that the whole matter is presented in an exhaustive fashion; the essentials are studied minutely, while the extremes, both of theory and practice, to which this form of disease is peculiarly subject, are handled with brevity and moderation. Every surgeon who devotes his attention to the ear or the head and neck in particular should be grateful to Dr. Braun for this magnificent volume.

A PRIMER FOR DIABETICS.

A Patient's Manual of Diabetes,[4] by Dr. HERBERT MOXON, is primarily intended for the information of the patient suffering from diabetes, and is based on a course of lectures to nurses delivered at the Perth Hospital, Western Australia. The author's aim is to give the patient a mental picture of his disease which will never be forgotten. With this object in view there are two chapters describing respectively "How the human engine works in health" and "How it works in diabetes." The physiological and pathological facts are set out in simple terms, so that if a patient is really interested (and no doubt some are) he may be better able to grasp what insulin can do for him, and why he must, even with insulin, keep strictly to a prescribed diet. The author next gives a short description of the symptoms and complications of diabetes, followed by three chapters on the principles of diabetic dietetics. In these chapters Dr. Moxon recommends chiefly the rules laid down by R. D. Lawrence, G. A. Harrison, and H. MacLean. The book includes also instructions for the administration of insulin and for urine testing. As a whole the book is well arranged and the instructions are clear and concise. Dr. Moxon appears to adhere to the method of a preliminary starvation of his patients, a plan which many authorities now consider unnecessary and even inadvisable. He gives expression to a grave warning on the dangers of pregnancy for a diabetic woman, even if treated with insulin. Yet it seems likely that an increasing number of women will pass safely through the dangers of childbirth, in spite of diabetes, provided insulin is scientifically employed. But these are minor criticisms; the book is written on sound lines and will prove helpful to those for whom it is intended.

BLOOD EXAMINATIONS.

DR. D. WARSAMY has produced in *Examen du Sang*[5] a comprehensive guide-book to the numerous laboratory methods which may be used to determine the histological, chemical, and serological constitution of the blood in health and disease. In the 472 pages there is much information that will be useful to the clinical pathologist. The arrangement of the book is awkward, involving much repetition and overlapping; it is a pity that the author has felt moved to include descriptions of methods and apparatus (with figures) which are now only of slight historical interest, and not employed in modern laboratories. Several methods for the estimation of haemoglobin are described, but Haldane's modification of Gower's haemoglobinometer, much used in this country, is not mentioned. The direction for the enumeration of platelets is scanty and the technique is not sufficiently detailed; there is no notice of the influence of operations or of splenectomy on the platelet count. The use of the word "monocyte" as a synonym for "red cell" is possibly an error. There is no mention of the presence of polychromasia in healthy blood, and no reference to the "reticulocytes" so much noted nowadays in connexion with the liver treatment of pernicious anaemia. The statement that in pernicious anaemia dwarf ("nains") cells predominate is, of course, not correct. In this account of the polymorphonuclear leucocyte Dr. Warsamy makes no mention of Arneth's classification of the nuclei, or of Schilling's haemogram. Under the section of microbiology there is much description and technical detail (for example, preparation of media), which belongs to textbooks of bacteriology.

THE TREATMENT OF THE CRIMINAL.

IN the *Journal* of September 22nd, 1928, there was an obituary notice of Dr. ALBERT WILSON, who was the author of a number of books and papers bearing on the subject of criminology and some of the psychological aspects of medicine. During the great war, though past the age of 60 years, he served with the French Red Cross, and issued some papers relating to military medicine and surgery. Two days before his death he had finished correcting the final proofs of a further volume, which has now been published under the title of *The Child of Circumstance: the Mystery of the Unborn*.[6] In addition to the author's preface, it contains a short notice of the life and work of Dr. Wilson, and two "forewords," one by the Rev. Dr. R. J. Campbell, and the other by Dr. J. S. Bolton, professor of mental diseases in Leeds University. Dr. Wilson's own statement of his book is that "the aim is to deal with the criminal from a scientific point of view, to ask what he is and why he is." It can scarcely be claimed, even by those to whom the personality of the author made the strongest appeal, that the result is commensurate with the aim. In the obituary notice above referred to we said that his first book "though readable and provocative of thought, and revealing deep sympathy with social misfits, inclined somewhat towards dogmatic statements on matters insusceptible of proof." The same phrase can truthfully be applied to his last book. It may perhaps be best described in Dr. Campbell's words as "a presentation of kindly and instructive recollections of past events and scenes in a varied professional career," and it is certainly, as Dr. Bolton says, "a work inspired by earnest and lofty motives." It is, however, very miscellaneous and disconnected. It contains a number of studies of individual criminals and delinquents, and of cases of double or multiple personality, some of which came under the personal observation of the author, but others of which

[5] *Examen du Sang.* Par Dr. D. Warsamy. Paris: E. Le François. 1928. (6½ × 10, pp. viii + 472; 44 figures, 2 plates. 50 fr.)

[6] *The Child of Circumstance: the Mystery of the Unborn.* By Albert Wilson, M.D.Ed. London: J. Bale, Sons and Danielsson, Ltd. 1928. (Demy 8vo, pp. xx + 420; 67 illustrations. 15s. net.)

are the staple cases of medical literature. There are chapters of some interest dealing with penal methods in Holland, Belgium, France, Germany, Spain, and America, both North and South. In addition, there are remarks, either collected into specific chapters, or scattered throughout a number of chapters, on sex and brain physiology, on heredity, on normal and abnormal psychology, on Freud and psycho-analysis, on the virtues of capital punishment and flogging, on Elizabeth Fry and John Howard, and, delightfully but quite inconsequentially, on Quakerism and on Lord Lister, of whom the author was a pupil, and to whom, as "my beloved chief," the book is dedicated. Throughout several of these sections one cannot escape the suspicion, often amounting to a conviction, that the facts given would not survive legal cross-examination or strictly scientific research; and it is certain that Dr. William McDougall and others would repudiate the views and ideas and teaching with which they are credited. It must be admitted, then, that the book is unreliable as a guide to the subjects with which it deals, but substantial parts of it are useful and interesting, and the whole is obviously the work of "a man of very generous instincts, whose innumerable acts of kindness were done in the most unobtrusive and self-effacing manner."

ANNALS OF MEDICAL HISTORY.

WITH the January number the first volume of the new series of the *Annals of Medical History*[7] begins. It is somewhat smaller in size and will in future be issued six instead of four times a year. The cover bears the portrait of Nicolaas Tulp (1593-1674), burgomaster of Amsterdam and lecturer on anatomy, in which capacity he lives in Rembrandt's famous picture of the "Anatomical Lecture"; he is referred to in an appreciation of the medical profession and the divine origin of medicine by Professor H. Burger, also of Amsterdam, who displays a remarkable and gratifying acquaintance with the works of British writers. The frontispiece represents William Cheselden (1688–1752), whom Mr. Mortimer Woolf mentions in "Some Personalities of the Hunterian Epoch," his presidential address to the Hunterian Society of London in 1927. Two fine addresses delivered in connexion with the tercentenary of the publication of Harvey's *De Motu Cordis* occupy rather less than half this instalment; the first, by Dr. Alfred E. Cohn of New York, was given on "The Development of the Harvean Circulation" before the Harvean Society of New York; the second, by Dr. E. B. Krumbhaar of Philadelphia, is based on the tercentenary exhibit of Harveiana by the College of Physicians of Philadelphia on March 22nd and 23rd, 1928, and deals with some biographical matters pertaining to the discovery of the circulation of the blood. The list of these possessions shows how rich the Philadelphia College is in Harvey relics, largely due to the activities and help of the late Dr. Weir Mitchell. In memory of William Potter, who for thirty years was president of the Board of Trustees of Jefferson Medical College, an annual lecture has been established, the first of which was delivered in Philadelphia on April 25th of last year by Sir StClair Thomson. Taking as his subject the strenuous life of a physician in the eighteenth century, this former president of the Medical Society of London discourses pleasantly on its founder, John Coakley Lettsom, and includes, among other well-executed illustrations, a map of Pennsylvania showing the districts called Lettsom and Fothergill. Dr. Burton Chance of Philadelphia gives an account, based on personal knowledge, of Squier Littell (1803–86), now almost forgotten, but deserving a better fate as one of the founders of ophthalmology in America. The activities of Martin Lister (1638–1712), zoologist, physician to Queen Anne, and a benefactor to the Ashmolean Museum at Oxford, are described by Mr. S. Wood, who appends extracts of medical interest from Lister's "Journey to Paris in 1698." After a scholarly editorial on ancient herbals there are a number of reviews of books, which, as usual, are well worth reading.

[7] *Annals of Medical History.* New Series, Vol. I, No. 1, January, 1929. Edited by Francis R. Packard, M.D. New York: P. B. Hoeber, Inc.; London: Baillière, Tindall and Cox. 1929. (Imp. 8vo, pp. 125; illustrated. Subscription in Great Britain £2 5s. per volume of six numbers.)

NOTES ON BOOKS.

DR. ARCHIBALD MALLOCH, who was inspired, like many others, by the late Sir William Osler with a devotional spirit for medical history and is now librarian of the Academy of Medicine, New York, gave a tercentenary address on *William Harvey*[8] to a joint meeting of the Harvard Medical Society and the Boston Medical History Club, held at the Peter Bent Brigham Hospital, with Professor Harvey Cushing in the chair. Reprinted from the *American Journal of Surgery*, this well-written and (as would be expected from Paul B. Hoeber's publications) appropriately illustrated address tells the story of Harvey's life and work, giving a human touch by a short account of his eccentricities. While paying a tribute to Sir D'Arcy Power's standard life and the late Sir Norman Moore's notice in the *Dictionary of National Biography*, Dr. Malloch has performed the now difficult task of adding something new to this much celebrated subject; he shows that Wilhelm Fitzer of Frankfurt, who published the original edition in 1628 of the *Exercitatio Anatomica de Motu Cordis*, was an Englishman, and raises the possibility that the poor paper on which the first edition was printed was a result of the Thirty Years War. The address is most conscientiously documented.

The 1929 edition of the *Yearbook of the Universities of the Empire*,[9] edited by T. S. STERLING, M.A., and published for the Universities Bureau of the British Empire, in form and contents closely resembles the issues of previous years. It comprises concise summaries from the calendars of seventy British universities, eliminating strictly local matters, and presenting information of more general interest. In relation to each university it gives an account of its curriculum, degrees, diplomas, fees, residential accommodation, libraries, and museums, and publishes a complete staff directory. Appendixes include guides to the conditions governing admission to various professions and careers; lists of university scholarships, fellowships, and grants for research; lists of professional schools, of the universities of the United Kingdom, and the distribution of subjects in which these universities severally may be said to specialize; lists of centres of research outside the universities; and a statement as to the conditions of admission of students from abroad into universities of the United Kingdom. A further appendix records the titles of theses accepted for the doctorate degree.

The forty-fifth annual issue of the *Year-Book of the Scientific and Learned Societies of Great Britain and Ireland*[10] comprises a record of the work done in science, literature, and art during the session 1927–28 by numerous societies and Government institutions. In form it resembles its predecessors, giving in relation to each learned society or institution a list of its officials, publications, and meetings, followed by a list of lectures and papers read before the society in the course of the session. In the section on medicine are included lists of papers issued by the Ministry of Health, the Medical Research Council, the British Medical Association, and the various medical societies. The publishers announce that in the next issue of the *Year-Book* they intend to mention only papers which, having been printed, have become available for reference.

Pleasantly written and with many illustrative examples to emphasize the conclusions, Dr. E. MARION COX's volume in the Mental Handicaps Series, edited by Dr. T. B. Hyslop, deals with *Mental Handicaps in Literature*.[11] The lets and hindrances which may obstruct the literary creative mind in its attempts at self-expression include, of course, bad heredity, alcohol and narcotics, the toxins of disease, poverty or riches, the mental atmosphere of the period, and writing for the daily press. Heredity, it is pointed out, is chiefly concerned in the transmission of a nervous state that may manifest itself in various forms of hypersensitiveness; some of these are definitely neuropathic, but others enable the poet, painter, or musician to achieve success. The frequent use of any narcotic or stimulant brings about in the long run a greater or less degree of physical deterioration of body and mind, but under medical control Dr. Cox admits that their use may be beneficial. With regard to the possibility that the toxaemia of chronic tuberculosis may stimulate literary brilliancy a caution is thrown ou

[10] *The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland.* Forty-fifth annual issue. London: C. Griffin and Co., Ltd. 1929. (Demy 8vo, pp. vii + 420. 10s. net.)

[11] *Mental Handicaps in Literature.* By Edwin Marion Cox, M.D. With a foreword by Theo. B. Hyslop, M.D. London: Baillière, Tindall and Cox. 1929. (Fcap. 8vo, pp. xi + 93. 3s. 6d. net.)

that this is unlikely to counterbalance the handicap in other directions. Dr. Hyslop provides a scholarly and philosophical foreword.

The campaign to eat more eggs has found a capable exponent in Mr. JAMES GATECLIFF, who has written a pamphlet entitled *Eggs: A Treatise on their Food Value*,[12] "dedicated to the housewives of England." Dr. G. Clark Trotter, who contributes a preface, points out that under the Sale of Food Order (1921) it is no offence to label foreign eggs with the word "English" so long as the words "fresh" or "new-laid" are omitted. He suggests that some cases of egg idiosyncrasy may perhaps be explained by the fact that the subjects have seldom or never had a really new-laid egg. The pamphlet contains sections on the food value of eggs, on the differences between British and imported eggs, and on methods of testing eggs for age. Mr. Gatecliff is anxious to free England from the "foreign yolk," and believes that an egg (English new-laid) a day will keep the doctor away.

PREPARATIONS AND APPLIANCES.

BACILLUS ACIDOPHILUS THERAPY.

MULFORD acidophilus bacillus blocks are designed to provide a palatable and portable method for carrying out *B. acidophilus* therapy.

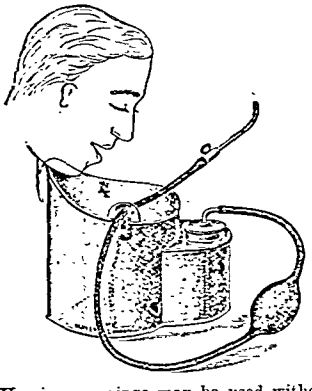
The object of this therapy is to suppress the growth of undesirable and toxic micro-organisms in the colon by encouraging the growth of the harmless *B. acidophilus*. Metchnikoff first drew general attention to the virtues of sour milk therapy, and subsequent research has shown that the beneficial effects of this treatment depend on the establishment of *B. acidophilus* as the dominant organism in the colonic flora.

Each block contains 150 billion living acidophilus bacilli of the Y type at the time of preparation, and it is estimated that at the expiration date marked on the packages 10 billion will still be viable. The blocks are made up with agar, and contain a certain quantity of milk sugar. They are coated with chocolate to prevent desiccation and to render them palatable. The dose recommended is 2 to 4 blocks a day for an adult. This treatment should be supplemented with lactose, which can be taken pure, or can be obtained from milk or fruits.

The makers (H. K. Mulford Company Ltd.) claim that their preparation constitutes the most convenient, attractive, palatable, and economical way of taking the acidophilus treatment.

A LAVAGE APPLIANCE.

Mr. Hugh E. Jones (Liverpool) writes: Unless a gravity douche-can is used, lavage of the accessory sinuses requires the patient, the nurse, and the surgeon between them to hold a syringe, and two more or less clumsy vessels—namely, the lotion vessel and the receiver.



The apparatus here illustrated is an attempt to overcome these difficulties by combining the lotion holder and the receiver in one appliance. The can is held by the patient, and the surgeon or nurse has both hands free to control the cannula and the syringe, which is securely held to the can by its detachable fastener. An assistant is not required, and, if necessary, the patient, by placing the can on the table, is able to perform the lavage unaided and in comparative comfort. If preferred the Higginson syringe may be used without the clip, which is detachable. The apparatus, which in the illustration is shown proportionately too large, can be used equally well for lavage of the eyes, ears, or any other part of the body. It has been made for me by Messrs. Mayer and Phelps.

ACETYL CHOLINE.

Acécoline is a French preparation of acetyl-choline hydrochloride which is marketed in this country by the Anglo-French Drug Co., Ltd. Acetyl choline is an extremely powerful stimulant of the parasympathetic system. A dose of one-thousandth of a milligram given intravenously in cats produces a measurable fall of blood pressure. The drug produces little or no action when given by the mouth, and the action when given intravenously is far too violent to be safe; therefore it is recommended for subcutaneous or intramuscular administration. The dose recommended is 20 to 200 mg. The effect of the drug in animals is to produce a very powerful but transient stimulation of the parasympathetic system. The reason for the transient action is that the drug is destroyed after contact with the blood for a few seconds. The vendors recommend acécoline for use in a large variety of conditions, including hypertension and a condition they term hyporagotonia

THE ORGANIZATION OF A MATERNITY SERVICE.*

BY

E. FARQUHAR MURRAY, M.D., F.R.C.S.,

HONORARY ASSISTANT GYNAECOLOGIST, ROYAL INFIRMARY, NEWCASTLE-ON-TYNE.

THE problems of maternity provide the greatest possible scope for organized preventive medicine. By means of an adequate maternity service many of the deaths and much invalidism resulting from the so-called "physiological process" of childbirth could be avoided.

The main criticism of the present system is that essential services are not available for many patients of the industrial class. The service rendered by a maternity hospital to such patients may be taken as an index of the essential requirements. It provides the following: (1) ante-natal supervision; (2) during the confinement, which takes place under the supervision of a midwife, clean surroundings, and an abundance of surgical dressings and lotions; (3) a doctor, who is on call to assist delivery, to repair lacerations, or to deal with complications; (4) good nursing; (5) post-natal supervision; (6) consultant services. Patients who have neither hospital facilities nor the means of obtaining the necessary assistance must be provided for, and it is for them that a maternity service should be organized.

Good nursing, the first essential of an efficient service, will never be obtained so long as handywomen are tolerated. Many patients cannot afford to pay for the services of a midwife as well as a doctor. In some districts the midwives are idle while handywomen flourish, and in others there are no midwives. For this state of affairs the profession is not to blame. The majority of patients would prefer to be under the care of a doctor, and we believe, and impress on our students, that medical supervision is necessary. As it is, many doctors working with handywomen are having a demand made on their time and energy for a most inadequate reward. Some doctors, indeed, refuse to attend a case unless a midwife is engaged as well, but it must be difficult to make this an inflexible rule. There are disadvantages to the patient both when the doctor works with a handywoman and when the midwife works on her own. In the former case the patient is denied trained nursing, and in the latter proper supervision. Midwives—either individually or as a team—should work in co-operation with a doctor; it is absurd to regard their book of rules as a substitute for medical supervision.

A maternity nursing service should be organized under direct medical supervision, and trained nursing should be placed at the disposal of a doctor whose patient is unable to make the necessary provision herself; the present almost independent position of midwives is not to the public welfare. As a temporary measure in teaching centres the pupil midwives, who are under the supervision of a trained midwife, might be brought into the service. By this means doctors would have nursing assistance and pupil midwives would gain experience, part of which the Central Midwives Board might very well allow to count for their qualification.

The Essentials of Maternity Care.

The following help would be given to the profession: (1) Urine specimens would be tested and visits paid to the patients to ensure that they were carrying out the rules of hygiene during the ante-natal period. (2) During the course of labour intelligent messages would be sent when a doctor's services were required, whether to assist the delivery, to deal with complications, or, should delivery have taken place during his absence, to repair lacerations. (3) Efficient nursing during the puerperium. (4) Additional service in cases of emergency, or for the relief of a nurse who has been without sleep for an unreasonable period, or for providing special nursing—as, for example, may be required in the after-care of lacerations which were threatening to become septic.

Such a nursing service would be a boon to the patients, to the profession, and to the midwives themselves. It would

* A paper read before the Edinburgh Obstetrical Society, March 13th, 1929.

guarantee to the latter constant employment, and almost certainly a better remuneration than they have at present. Under the supervision of a sister midwife it would ensure the maintenance of accurate temperature charts, and thus lead to the earlier recognition of the onset of inflammatory processes. The nurses would report the presence of a temperature to the sister midwife, who would at once inform the doctor. The present system of allowing a midwife full charge (subject to her rules) is fundamentally wrong, and it will never be righted until there is properly organized medical supervision of this branch of nursing.

Surgical dressings and lotions, available in good-class practice and in maternity hospitals, are often scant or absent in industrial practice. Such dressings should be supplied to the poorest patients free of charge; to others, according to their means, for part or the whole of the cost. The appropriate dressings would be accouchement sheets, wool, binder, diapers, and towels. A special package consisting of a pair of sheets might be available for use during the puerperium. The dressings would be sterilized, and the nurse would be responsible for any that should be returned.

Ante-natal Supervision.

The value of this ante-natal care cannot be overestimated. It is one of the blots on the present system that a number of women with the most flagrant pelvic contractions and obvious malpresentations are often well advanced in labour before the abnormalities are recognized, or that renal complications, readily detectable in the course of routine ante-natal examination, should be allowed to develop until the patient is admitted to a maternity hospital in a moribund condition. Ante-natal care, the very essence of intelligent midwifery, must be available for every pregnant woman, and clinics at which such care can be given are required above all by the doctor in industrial practice. Ante-natal examinations take more time than the busy doctor can spare during his ordinary consulting hours, and, in any case, prospective mothers would prefer not to take their place in a waiting room filled with patients of both sexes. The alternative of conducting the examination in a working-class dwelling is hardly better. The existing ante-natal centres provide examination rooms, with nurses in attendance, for a type of investigation about which women are very sensitive; the examination in the vast majority of cases is abdominal, but women know that a vaginal examination may be made. There is privacy, and only one sex is present.

The Function of the General Practitioner.

The staffing of the centres is so far variable. Specialists and whole-time officers figure prominently, and both have done invaluable work. Ante-natal care is, however, the business of the general practitioner. Child-bearing is responsible for much ill health, and it is well known how pre-existing constitutional disease may influence the pregnant state. Those who are responsible for the medical care of potential mothers and are engaged in obstetric practice should also be responsible for their welfare during all the phases of maternity. Doctors who practise in the area and are called in by the midwives should, as soon as it can be arranged, be on the staff of the ante-natal centres. If valuable clinical experience provided by the centres is absorbed by specialists and whole-time officers it will be seriously detrimental to the efficiency of those engaged in general practice. Doctors, moreover, have hitherto been denied supervision of cases attended by midwives unless the midwife has called them in. Now that ante-natal centres are being established there is a tendency for whole-time officers and specialists to deal directly with the midwives, this again excluding the doctors from their proper place in maternity work.

In every area, however, there are many doctors who are keen and competent to do the work of the centres. Their appointment might be made contingent on the possession of some agreed qualification—for example, a diploma in obstetrics, or evidence of post-graduate study, or of a period of residence in a maternity hospital. There is no valid reason why the clinics should not be conducted by several doctors working on a time-table of attendance and a suitable system of reliefs. Whole-time officers may very properly be in charge when, for geographical reasons, it is not possible to obtain the necessary medical supervision locally, or during periods of epidemic when doctors are overwhelmed with urgent work.

Details of Organization.

An organized maternity service for the industrial class would work somewhat as follows: (1) Each woman would select one of the doctors on the obstetric panel and would enter her name at the nursing centre. (2) The doctor selected would interview the patient in his consulting room, investigate any complaint, and instruct her in the ante-natal routine; (3) the nursing service would arrange for the routine urine testing and health visits. (4) The ante-natal examination would be made either at the patient's house or at a centre; in the former instance the nursing service would co-operate. (5) Patients would have indicated before the onset of labour if they wished the doctor to be present at the confinement or merely be on call if required; in the former instance the doctor would receive accurate reports from the midwife, and in the latter he might not be required at all. (6) Certain routine visits would be paid during the puerperium. (7) The total demand made on a doctor would in many cases consist merely of a few routine visits, and if more active assistance were required, especially at night, his expenditure of time and energy would be reduced to a minimum.

The practical side of midwifery must be as highly organized as possible. Handywomen are responsible for many false calls, hurried labours, and much bad nursing. They must be abolished and the maximum of trained nursing assistance placed at the disposal of the profession. Consultant services should be available during the whole of pregnancy and the puerperium for patients who cannot afford a private consultation. It has been arranged that women who have midwives to attend them can have the services of a medical practitioner at all stages; there is no reason why consultant services should not be available also. Expert opinions in puerperal pyrexia can be obtained in many areas and on ante-natal conditions in others, but so far no provision has been made to give doctors expert assistance during labour. In large industrial areas an emergency service should be organized. This would provide at short notice a nurse, blankets, hot-water bottles, transfusion apparatus, solutions, and, if necessary, a specialist. There are many conditions in which, instead of rushing a shocked and collapsed patient to hospital for nursing and specialist aid, the specialist and nurse should be rushed to the patient. The failure of many of the smaller hospitals to provide beds for maternity cases often forces doctors to deal with major surgical problems in unsuitable surroundings, or to lose much valuable time by sending their patients on a long journey to a maternity hospital.

General Conclusions.

The cost of many of these suggestions can be met without making any, or, at most, only reasonable, demands on the State or the approved societies. The majority of patients under discussion try to meet the expenses incurred by means of a maternity benefit. This benefit is paid with equal readiness in successful cases, in cases in which the child is stillborn, or in which the mother dies of puerperal sepsis. Such a reward may be called a maternity benefit, but it certainly does not benefit maternity. A benefit to be of any real value should stipulate and make provision for medical supervision and nursing.

Criticism is always rife when suggestions are made that all is not well with the present system. Women have been delivered, and have made excellent recoveries, in the most squalid surroundings and without any medical attention. This is a commonplace, otherwise the nation would have disappeared long ago. The profession cannot allow the continued high mortality and morbidity rate to become a commonplace; it is a dread reality. If, as a profession, we allow the public to believe that a handywoman can provide adequate nursing service, or that we approve of the independent action of midwives, any efforts to improve the maternity service will be futile.

SATURDAY, APRIL 13TH, 1929.

RECURRENT TOXAEMIAS OF PREGNANCY.

OUR ignorance of the toxaemias of pregnancy is shown by the fact that there is at present no general agreement as to their classification. All workers, indeed, concur in differentiating pernicious vomiting, acute hepatic atrophy of pregnancy, and eclampsia; but the cases in which albuminuria, unaccompanied by convulsions, appears during the later months of pregnancy are the despair of the systematist, and are likely to remain so until more definite insight into their etiology has been gained.

Stander, in the elaborate monograph on the toxaemias of pregnancy which constitutes the current number of *Medicine*, recognizes, in addition to the three above-mentioned types of toxaemia, "low reserve kidney," nephritis complicating pregnancy, and pre-eclampsia. Though some purists may object to the application of the term "pre-eclampsia" to a state in which convulsions do not necessarily develop, the term has its value in keeping before our minds a potential danger. A patient in the later stages of pregnancy, showing a high grade of albuminuria, a raised blood pressure, headache, nausea, epigastric pain, and visual disturbances, is to the experienced obstetrician a potential eclamptic even though no fits develop. Convulsions are no doubt impressive, but they are merely a symptom and not the disease. It is, however, in the remaining types—"low reserve kidney" and nephritis complicating pregnancy—that we meet with real difficulty, both in our classification and in the management of cases. According to Stander the low reserve kidney, or pregnancy nephropathy, is characterized by moderate albuminuria and a temporary rise in blood pressure, without change in the blood chemistry, appearing during the later months of pregnancy. The condition may or may not recur in subsequent pregnancies, but, if it does, it is not usually more severe than in the first pregnancy and leaves no permanent renal damage. In nephritis complicating pregnancy, on the other hand, symptoms appear earlier, the blood pressure is higher, and the amount of albumin present in the urine is greater in each successive pregnancy. An appreciable rise in the non-protein nitrogen of the blood may occur, and permanent renal damage may result. Stander believes that these nephritic cases can probably be subdivided further into two groups, in one of which the renal lesion antedates the pregnancy and is due to some other cause, while in the other "repeated pregnancies may have played a role in the development of the nephritis." It will be noted that the differentiation of the "low reserve kidney" from pre-eclampsia is by no means sharp, and it is permissible to suggest that the former may be merely a mild grade of the latter. It will also be remarked that the question of permanent renal damage arising directly out of pregnancy *qua se*, as distinct from the aggravation of an existing nephritis by supervening pregnancy, is left undetermined

Dr. James Young has recently discussed in our columns (January 19th, p. 91) the obstetric histories of eclamptics and albuminuria, and has shown that, contrary to current teaching, toxaemic conditions tend to recur in subsequent gestations. Eclampsia, pre-eclampsia, and the "low reserve kidney" of Stander are apparently conditions characterized by a well-marked tendency to recurrence. This finding is of obvious practical significance, since it indicates the necessity of especially careful ante-natal supervision in the subsequent pregnancies of patients who have once suffered from a pregnancy toxaemia; the gravest of all the toxaemias of late pregnancy—eclampsia—is itself not infrequently recurrent. A further problem studied by Young is whether the reappearance of albumin in the urine in a second pregnancy is purely secondary to a recurrent toxaemia, or the expression of a chronic renal defect aggravated by each succeeding pregnancy. In his view the reappearance of albuminuria is the direct result of the recurrence of the toxaemia, and is not due to persistence of the original renal damage caused by the first toxaemic pregnancy. Though this question may at first sight appear to be of merely theoretical interest, it is actually of very great practical importance, since the possible risk of permanent damage to the kidney must affect the medical attendant's views as to the advisability of further pregnancies and as to the necessity of early induction of labour. Young's opinion is based on the observation, confirmed by Dr. Jessie Sym in her study of the renal function and cardio-vascular system in 139 patients who had suffered from eclampsia or albuminuria, that a recurrent attack of albuminuria differs in no essential from the primary attack. In Jessie Sym's series a diagnosis of chronic renal disease was considered to be justifiable in 3 per cent. of the post-eclamptics and in 8 per cent. of the post-albuminurics. When we consider that it is not improbable that in some of these patients renal disease may have been present before the toxaemia, since chronic nephritis may give rise to no obvious symptoms, it would seem that the toxaemias of pregnancy rarely produce permanent renal damage.

In our present issue (p. 674) Mr. G. F. Gibberd emphasizes the frequency with which pregnancy albuminurias recur, and finds in this recurrence evidence of an "occult nephritis" persisting from the first pregnancy, but only demonstrable by "the most delicate test of renal function which we possess"—that is, by another pregnancy. That pregnancy aggravates any existing renal damage is generally acknowledged, but if we admit that grades of renal damage exist which cannot be detected until submitted to the test of pregnancy, it may be argued that even primiparae who develop albuminuria during pregnancy have in reality been suffering from a pre-existing occult nephritis. Until we know more of the underlying conditions which produce the toxaemias of pregnancy it would seem as rational to assume that they tend to recur in the same individual as to postulate the existence of an occult nephritis in those cases only revealed by the occurrence of pregnancy. The only evidence we have of the possibility of such a condition is supplied by the work of Professor F. J. Browne on oxalate nephritis in rabbits.

Meanwhile it is important for the practitioner to recognize that, contrary to time-honoured beliefs, toxaemia frequently recurs in successive pregnancies, and that in some cases permanent renal damage may result. More information would appear to be needed as to the frequency of such damage. Above all, we need more exact data as to the relationship of permanent damage to the duration of the toxaemia if patients are to be saved from this untoward result by a timely induction.

MEDICAL SCHOOLS AND HOSPITALS.

MEMBERS of the medical profession of Melbourne, especially those engaged in university work, have for many years expressed their dissatisfaction with the situation they had inherited from their fathers. They found many separate and conflicting interests. The hospitals were scattered haphazard about the city, with no relation to present-day needs. The university medical school was disjointed in its parts, and totally unrelated to the hospitals where its students received their clinical instruction. In these circumstances it was generally felt that the Melbourne problem ought to be approached from the broadest possible point of view. The Government of the State of Victoria accordingly sent out three representatives in 1927 upon a mission of inquiry to study conditions in other countries. Their report was unanimously in favour of a complete reorganization scheme whereby medical schools and hospitals and institutions for research would be combined at a common centre. We have already noticed this joint report,[1] and now at page 700 this week we give a summary of the independent observations of Professor R. J. A. Berry which were published a year later. They are in full agreement with those of the joint report signed by himself and his two colleagues, but their range is wider, since Professor Berry visited and commented upon British institutions and conditions as well as Canadian and American.

The idea of unity of design and working of medical school and hospital is no new one to us. We have an old tradition of their essential unity. The several London medical schools are each part and parcel of the hospital with which they are connected and from which they sprang and received their name, at least as far as clinical teaching and the later subjects of the curriculum are concerned. Any separation in these respects is inconceivable. That such symbiosis is a mutual benefit is certain. There is usually more than this unity between school and hospital, for all the laboratory equipment, both for the preliminary sciences, anatomy and physiology, pathology and research, is as a rule within the hospital precincts or in their immediate neighbourhood. That this is felt as the natural and practical arrangement, one that has grown up with time, is perhaps due to the conveniently moderate size of each of these medical centres. Other problems come into play where a whole university school is involved, and particularly where this school is superimposed upon long-existing clinical institutions. In a university centre the number of the students may be so great as to make concentration difficult, especially in an old city. Yet these difficulties have been overcome, Professor Berry assures us, on the other side of the Atlantic by the erection of vast buildings towering up into the sky, the many radiating arms of the central block carrying all the ancillary departments, which have direct access to the core, which is the hospital; and the hospital in its turn has direct contact with every research department. It is a great conception, and a gigantic reproduction, on symmetrical lines, of any one of the several London medical schools. This is what he and his colleagues would like to see in Melbourne. It is certain that where there is a university medical school in any city there should be direct connexion between it and any hospital or other clinical institution within the area which is suitable for clinical teaching; but there may be some question as to whether all these institutes can conveniently, and with equal advantage to the patients, be accommodated at some one strategic site, instead of being scattered throughout the city. The University of London, for instance, allows the first-year's course of study to be taken at a school of university rank which is not strictly a medical school, and more than one of the London medical schools conducts the first two years' study at a place apart from the hospital with which it is associated; and these arrangements are not unsuccessful.

Professor Berry's observations upon hospital policy are of equal interest. He criticizes the traditional idea of the British voluntary hospital as an institution for the poor only, and dislikes hospitals under bureaucratic control. He finds his ideal in the self-supporting hospitals of Canada and the United States, where all the patients pay or are paid for, and where the work of the medical staff receives its proper and natural recognition. We in this country are on the eve of great changes in our hospital arrangements. The Local Government Act of 1929 opens a new outlook upon hospital administration. The old-time Poor Law infirmaries will now pass into the control of more modern and as a rule larger statutory authorities. These bodies have already had wide experience of administration, though that of county councils in some spheres of public health has been much less than that of county boroughs, or even, in some cases, of their own county districts; and in neither case, apart from mental hospitals and hospitals for infectious diseases, have they had much experience in the management of hospitals of a general kind. The credit of the voluntary hospitals is to-day higher than it has ever been, and that credit is by general consent deserved. We may hope that when these two parties, both of high honour and estate, and both vitally concerned with hospital administration, meet, as they must meet, to discuss their mutual relations, they will have in mind no consideration other than the common advantage.

[1] *British Medical Journal*, November 12th, 1927, p. 892.

RADIUM POLICY.

CAREFUL readers of our Parliamentary Notes will have observed during the past five months a succession of brief statements by Ministers in reply to questions in the House of Commons on the subject of radium. As far back as November 19th Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, said that the radium requirements of this country in relation to possible sources of supply were under consideration by a subcommittee of the Committee of Civil Research; he hoped that its report would be presented shortly. This stock answer was repeated, with slight variations, by the Minister of Health or his deputy on several occasions. Thus Mr. Chamberlain, on February 7th, said that the Government would consider the whole question of the purchase of radium when the subcommittee of the Committee of Civil Research which was looking into the matter had reported. Then, on February 27th, Mr. Locker Lampson, Under Secretary of State for Foreig Affairs, said that the Government was expecting receive in a few weeks' time a report on the radiu requirements of the country and the possible sour of supply; and that until this report had been con sidered the Government could not judge whether to ask the League of Nations to institute an inquiry into the conditions of production and sale of radium. On March 25th Sir Kingsley Wood said that the committee's report had been received, and would be published in full very shortly. He added that the intentions of the Government in the matter would be

made known immediately on the reassembly of Parliament after the Easter recess.

These not very illuminating replies are all that the medical profession and the House of Commons have been vouchsafed on a question of great importance to medicine and the public. Rumour speaks of an intention to set up a public authority for the purpose of holding and distributing radium for medical and other purposes. To what extent responsible medical advice is being sought and taken in this matter has not yet been divulged. The production and the State purchase of radium may be problems of economic and political rather than of medical concern; but its accurate preparation and screening for clinical use is a combined problem of physics and medicine, and the distribution of the element and its emanations is essentially a problem depending for its successful solution on the advice of those members of the medical profession who are fully aware of the most recent physical, clinical, and pathological work bearing on radium, and who have considerable experience in its application. Any scheme of distribution will succeed or fail according to whether it has or has not behind it the approval and support of the medical profession, through whom alone treatment by radium can be administered.

So far as we are aware, the personnel of the radium subcommittee of the Committee of Civil Research has not been publicly announced. It may or may not contain medical representatives; it may or may not have consulted with those members of our profession who are best fitted to express opinions on the medical aspects of the subject under investigation. Yet on the strength of this subcommittee's report the Government is understood to be preparing a policy which the Prime Minister will announce in the House of Commons soon after Parliament reassembles on April 15th. There will be room for serious misgivings if the announcement of any policy is concerned with questions other than those of the sources of supply and methods of purchase. Fortunately there are now representatives of medicine and surgery in both Houses, and we rely on them, in the first instance, to take steps to safeguard the position.

THE ORIGINS OF SCIENTIFIC THOUGHT.

THERE is no more extraordinary phase in the history of thought than that exhibited by the rationalizing tendency of early Greek philosophy. The process by which these ancient thinkers came to realize that the world in which they lived worked according to reasonable and discoverable laws represents the period of gestation of science. The subject will always be of interest to the student of human beginnings. Professor Léon Robin, in *Greek Thought and the Origins of the Scientific Spirit*,[1] has essayed to cover again the area so admirably treated by Professor John Burnet in his well-known *Early Greek Philosophy*. The two books are somewhat similar in design, but that of Professor Robin has the great advantage of following the theme throughout Greek history instead of stopping short with the better-known thinkers of the fourth century B.C. There are two chief obstacles to the tracing of the early history of scientific thought. First is the fact that the Greek man of science is not completely distinguished from the philosopher, in the sense that he has for his object the *logos* rather than the *pragma*, the intelligible rather than the fact. His gaze is bent on eternal forms and turned away from matter. Thus the Greeks tended to excel rather in what they held to be the changeless verities of mathematics than in those "servile activities" which we nowadays elicit by the simple processes of observation and experiment. To understand Greek science we must therefore seek to understand the mental processes of the Greeks. The study is essentially psychological. In this matter Professor Robin is a reliable and useful guide. The second difficulty arises from the extremely broken character of the record, especially that of the earliest period. We have, for the most part, to depend upon fragments and quotations by later writers. There is one group of early scientific authors, however, of whom we have extensive survivals. These are the medical writers, who have left large remains in the so-called "Hippocratic Collection." Thus, for instance, the *Sacred Disease* and the *Airs, Waters, and Places* present us with a most important philosophical standpoint which is very different from that of the work *On Generation*, that accords with the "Pneumatic" school, or, again, from the Heracletian treatise *On Diet*. The Hippocratic Collection contains, in fact, the earliest complete scientific works that we possess. It is thus, in our opinion, a very grave oversight of Professor Robin that he passes these important and interesting works with scarcely a mention. Aristotle has fared better than Hippocrates at Professor Robin's hands. He has, however, provided us with but little reference to the great biological achievements of "the philosopher." Thus, Professor Robin's work gives the impression of looking at science from the outside and never entering into the spirit which moves it. His work is essentially a discussion of the impact of science on philosophy. Now this impact depends on scientific achievement, and the scientific control of nature in antiquity was relatively insignificant. Thus the science that really influenced the thought of antiquity was neither experimental nor mathematical nor biological science, but rather observational astronomy. This led to the view that the life of man is subject to the revolutions of the stars, and that his soul alone is free. With such a conception in men's minds there arose the philosophical schools that became so popular in the later Greek period—Stoicism, Neo-Platonism, Scepticism, and the rest. It is in the treatment of these rather than in the early period that Professor Robin is at his best.

[1] *Greek Thought and the Origins of the Scientific Spirit*. By Léon Robin, Professor at the Faculty of Letters of the University of Paris. Translated by M. R. Dobie. The History of Civilization. Edited by C. K. Ogden. London: Kegan Paul, Trench, Trubner and Co., Ltd.; New York: A. Knopf. 1928. (6 × 9¼, pp. xx + 409; 1 map. 21s. net.)

STANDARDIZATION OF THERAPEUTIC AND DIETETIC PREPARATIONS.

THE third annual report of the pharmacological laboratories of the Pharmaceutical Society contains an interesting account of the way this useful institution is developing. The department was established to provide impartial tests of substances coming or likely to come within the scope of the Therapeutic Substances Act. This work is steadily increasing, and in the year under review 156 samples were examined, as against 126 in the preceding year. The chief substances investigated were pituitary extract, digitalis, squills, and ergot. In pursuance of the idea of providing biological tests for the activity of important drugs, a nutrition department was opened for the purpose of determining the vitamin content of cod-liver oil. The work in this respect was not very great, but a big demand developed for the testing of the vitamin content of food products, and the laboratory decided to accept such substances. As a result the department has examined 184 samples for the vitamin content, as against only 43 in the preceding year. The laboratory, in doing this work, is undoubtedly performing a very useful public service. There is always a tendency for the optimism of commercial enterprise to carry the claims made for their products beyond the limit of demonstrable fact. As long as firms could not obtain any measurement of the vitamin content of their preparations without going to the great expense of establishing a special laboratory for such determinations, it was difficult

to criticize them when they claimed for their preparations merits that biological tests did not support. Now, however, that it is possible for any firm to acquire this information a much higher standard of accuracy can reasonably be demanded. This, of course, will be all to the advantage of firms which have advertised their products with a sense of responsibility. An investigation of particular interest to the public health was the determination of the vitamin content of margarine. The production of this preparation with a vitamin content equivalent to that of butter is obviously an important step towards the prevention of rickets among the poorest sections of the population. The medical profession has reason to be grateful to the Pharmaceutical Society for the work its laboratory is doing in helping to promote a high standard of quality in drugs and food products.

COOKERY AND CHARACTER.

To judge from a recent correspondence in the *Times*, many English persons prefer French cooking to that of their own country, and we are not altogether disposed to cavil at their judgement. Almost the best that has been said by a stranger on behalf of English food is that it conceals sterling worth behind an unprepossessing exterior. It is a pleasing pastime to correlate the character of a people with its national dishes, though the question remains whether the sturdy independence of English character, the solid English virtues, are the products of the roast beef of old England or vice versa. What, in fact, is the true causality sequence underlying the aphorism "Mann ist was er isst"? Is it English Puritanism, an austere uneasiness at associating pleasure with the fulfilment of an appetite, that has determined what foreigners regard as the monotony and unpalatability of English food? The Englishman, it has been said, will not take a walk for the pleasure of walking, but only in pursuit of a bird, a beast, or a golf ball; equally he will not eat to enjoy an aesthetic experience, but only to appease hunger or for health's sake. It is possible, however, that the simplicity and lack of variety of English food may be explained by the fact that since the year 1066 no invader has landed on these shores. Soldiers have been great missionaries of culinary practice; wherever they went they insisted on having their accustomed fare, and they taught the women of the invaded country the art of preparing it. Thus, whatever else may have been the outcome of a war in past centuries, the nation's culinary repertoire was enriched with new recipes, which were handed down with more or less change through generations of housewives. This may account, in part at least, for the multitudinous elements that compose the French cuisine. Culinary modes, brought in turn by Englishmen, Germans, and the soldiers of many other nations, have been blended to form a new style of cookery, a French style, as varied yet as individual and homogeneous as the race that has been produced in England by the blending of Saxon, Norman, and Celt. The case of America is said to be somewhat similar. Invaded throughout the nineteenth century by hordes of immigrants from many lands, it has evolved an eclectic kitchen which ranks second only to that of France. The effect upon the evolution of American cookery of the laws restricting immigration is a subject of real disquiet among serious epicures. Fortunately there are many in this country who are concerned at least as much with the appetizing quality of food as with its vitamin content, and there is some solace in the reflection that it was the most English of essayists, Charles Lamb, who wrote: "I am no Quaker at my food. I confess I am not indifferent to the kinds of it. Those unctuous morsels . . . were not made to be received with dispassionate services. I hate a man who swallows it affecting not to know what he is eating. I suspect his taste in higher matters."

PATHOLOGICAL MUSEUM AT THE MANCHESTER MEETING.

THE Pathological Museum which is being organized in connexion with the Annual Meeting of the British Medical Association in Manchester next July will be arranged under the following heads: (1) Exhibits bearing on discussions and papers to the various Sections. (2) Specimens and illustrations relating to any recent research work. (3) Instruments relating to clinical diagnosis and pathological investigation. (4) Individual specimens of special interest, or a series illustrating some special subject. (5) Any exhibits of general interest. The organizing committee desires to enlist the co-operation of all willing to provide material. The museum will occupy a central position in the same building as that in which the sectional work of the meeting will take place, and will be easy of access. Every care will be taken of the specimens, and the contents of the museum will be insured. It is hoped to make arrangements whereby exhibitors may have an opportunity of demonstrating their specimens. In order to facilitate arrangements intending exhibitors are asked to give notice of their intention at the earliest possible date. The secretaries of the Museum Committee are Dr. William Susman and Dr. H. L. Sheehan, Department of Pathology, Manchester University.

MANKIND AND POLITICAL ARITHMETIC.

IN view of the demonstrable failure of a number of eminent and exceedingly well-qualified men in times past, from Sir William Petty downwards, to forecast correctly the growth of national or world population and the conditions of human existence at future periods, it is not necessary to take too seriously similar speculations on such matters, even though they are now based on more exact statistical data. Nevertheless, a concise and convenient volume entitled *The Shadow of the World's Future*,[1] by Sir George Knibbs, well known for many years as statistician to the Commonwealth of Australia, is worthy of attention. The impending tragedy intended to be indicated by the title is this: that "if the population of the world continues to increase at the present rate of 1 per cent. per annum it will within two centuries exceed the maximum which the earth can support and feed." Even those of us who may remain sceptical and unalarmed in the face of this proposition must admit that the problem of population (or, perhaps better, the problems of populations) is very important, and is now in many parts of the world giving rise to questions which have immediately to be faced. In fact, such questions are attracting widespread attention, and it is perhaps as well that an international conference met in Geneva in 1927 to discuss them, and that an international union, with its headquarters in Paris, has been formed to promote the scientific investigation of various aspects of the subject. Sir George Knibbs holds that "the population question is of the first order of importance for every person who has an interest in his country's future, or in his children and children's children"; and that "the difficulties of the near future relate specially to food supplies and to economic organization," and "are of a character which does not give any ground for the hope that they will automatically adjust themselves." In the earlier two-thirds of his book he gives a large number of statistics, and statistical tables, of a kind not to be found at all, or at least so conveniently, elsewhere. All these are worthy of examination, though no doubt many of them require the critical examination and comment of other statisticians. The latter part of the book is devoted to more general propositions or considerations, and some of these are important and valuable, whatever be the truth of the figures previously

[1] *The Shadow of the World's Future*. By Sir George Handley Knibbs, C.M.G., F.R.A.S. London: E. Benn, Ltd. 1928. (Demy 8vo, pp. 132. 10s. 6d. net.)

given or of the deductions drawn therefrom. The main factors reviewed in these later chapters are indicated by three of their titles: "The migration of populations," "International economics and migration," "World population and nationalism." The contention is that the population problem is not merely an economist's problem, but the greatest of all political questions; and the nature of the conditions to be considered in its solution may be discovered in the following quotations. "World conditions are such that the rights of all peoples will have to be equitably considered if the world desires peace. This involves the admixture of peoples who have attained to very different degrees of culture or civilization, and it is full of difficulty." "It will be necessary for all peoples to realize that effective occupation is the only safeguard ultimately of their rights. Dense and expanding populations will be compelled to challenge cases of ineffective occupation, and that will be one of the great problems of the very near future." "Spirit is a limiting factor to the growth of the human race," and "a more humble life physically with a deeper regard for the higher issues is a *sine qua non* if it be desired to see the earth covered with contented peoples whose well-being is assured and whose living is a disclosure of generous attitude and noble purpose."

HICKMAN MEMORIAL FUND.

A LETTER from the organizing committee of the Hickman Memorial Fund appeared in our issue of December 8th last (p. 1065), following a number of earlier references to the same subject. A committee meeting of the fund was held on March 27th, with Lord Dawson in the chair, when the possibility of fulfilling all the objectives of the appeal was fully discussed. It was decided that the fund was as yet inadequate to restore Hickman's tombstone, to provide a memorial tablet for Bromfield Parish Church, to present a portrait to the Royal Society of Medicine, and to found a Hickman Medal for original work of merit in anaesthesia. Subscriptions already received will be sufficient to deal with the three former, but not for the medal. It was felt by the committee that in no better way can the object of this appeal succeed both in honouring Hickman's name and in serving a useful purpose than by stimulating research for new anaesthetics and methods, in which it must be admitted British anaesthetists have for some decades rather followed than initiated. The appeal will therefore not be closed for the present, in the hope that some who have forgotten or overlooked the matter, or have not appreciated its practical as well as historical importance, and others who may feel that they are indebted to anaesthesia, may yet give it their support. A list of subscribers will be published when the fund is closed. Mr. V. Warren Low, F.R.C.S. (76, Harley Street, W.1), is the honorary treasurer.

OCCUPATIONAL DISEASES.

THE fourth congress of the Permanent International Committee on Occupational Diseases was held in Lyons at the close of last week under the presidency of Professor Etienne Martin. It may be remarked that in one respect a difficulty presents itself to-day which did not trouble Rammazini—one of the pioneers in this field—who wrote a book in the eighteenth century on the diseases of industrial workers. Interchange of views and experience was easy at that time, when Latin was the universal language of science; at Lyons, however, representatives of eighteen different countries were met to pool their information, and the aid of skilled translators had to be invoked. The three main subjects discussed were the silicoses and pneumoconioses, cataract of industrial origin, and the relation between the endocrine organs and the industrial toxaemias. Professor E. L. Collis of Cardiff opened the first discussion, and was supported by Drs. A. Mavrogordato and L. G. Irvine of Johannesburg. Many speakers followed, but the principal conclusion reached was a rather negative one, considerable doubt being thrown upon the possibility of diagnosing dust diseases by means of *x* rays. Professor Rollet of Lyons opened a discussion on industrial cataract, and Professor Ferrannini of Cagliari introduced the topic of the relation between the endocrine glands and industry. Among other papers may be mentioned one on the infection of farm workers by *B. abortus*, contributed by Dr. Theodore Thompson. In addition to medical practitioners, representatives of employers and workpeople were also present and joined in the debates. The British Government was represented by Dr. J. C. Bridge of the Home Office and Dr. S. W. Fisher of the Department of Mines. The social side of the programme was well arranged, and included a visit to the glass works of Givors, receptions by the Mayor of Lyons and the Lyons Chamber of Commerce, and a dinner at the Faculty of Medicine, when eloquent speeches were made by Professor Martin, Professor Devoto of Milan, Sir Thomas Oliver, and others. It was decided that the next congress should be held at Geneva in the summer of 1931, as an acknowledgement of Dr. Carozzi's valuable work in connexion with this year's meeting at Lyons.

THE INSURANCE PRACTITIONER'S HANDBOOK.

THE third edition of the well-known book entitled *Medical Insurance Practice*,[1] by Mr. R. W. Harris and Mr. Leonard Shoeten Sack, has now been published by the British Medical Association, with the approval of the National Insurance Defence Trust. The reason for the changed auspices under which the volume is issued is stated by Dr. H. G. Dain in a foreword: "The Insurance Acts Committee is so convinced of the usefulness of this book of reference that it has gladly acceded to the request of the authors to take over the publication of this third edition in the anticipation that by so doing it can be produced in a form and at a price that will tempt every insurance doctor and lay administrator to possess a copy. The possession of the book will lead to its regular use, and its regular use when new points or difficulties crop up will greatly promote smooth working and save much time and correspondence." The reason is good and sufficient, and the desired result should be forthcoming, for the book, in price, in format, in arrangement, in clearness, and in accuracy, is all that could be desired. It contains everything that it is necessary for an insurance practitioner to know, and almost everything that it is essential for the most responsible administrator (whether an official of an approved society or an official or member of an Insurance Committee) to know with regard to medical benefit. Indeed, it may be that in respect of some portion of its appendixes it contains even more than they need to know. The revision for this edition has been done by the authors, and it has been done with extraordinary care and (as far as a critical perusal has been able to discover) with absolute accuracy. No one in possession of this book should have any real difficulty in referring to the particular point on which he seeks information or elucidation, and no such person need hesitate to place complete reliance upon the statements and explanations which he finds—unless, indeed, the facts have altered since the date of publication, and, in any such event, there is no doubt that a fourth edition will bring matters up to date. All the omissions—and there are a good many—from this edition have been judiciously made, an account of all the most recent alterations of

[1] *Medical Insurance Practice.* By R. W. Harris, late Assistant Secretary in the Ministry of Health, and Leonard Shoeten Sack of the Middle Temple, barrister-at-law. Third edition. London: British Medical Association. 1929. (Cr. 8vo, pp. xv + 368. 3s.)

procedure has been incorporated, and wherever there has seemed the least possibility of this being advisable, even the clear statements of earlier editions have been made yet more clear. On one point only should we desire an additional note, and this is on a matter which is unessential. In dealing with "Records of illness" reference is made to the departmental committee of 1920 which dealt with the question of the form of record, and in Appendix 12 some extracts from the report of that committee are given. It should perhaps be mentioned that with regard to the recommendation that a record of all attendances and visits should be required, several members who agreed to this recommendation have since stated that, as the result of actual experience, they are no longer of the same opinion; and the Conference of Representatives of Local Medical and Panel Committees has on several occasions expressed the opinion that this requirement is unnecessary and may even be harmful. In their preface to the first edition of the book the authors said: "This book is addressed to the busy general practitioner. While excluding matters too remote to be of interest to him, we have endeavoured to avoid leaving unanswered any question arising in his daily insurance work on which he is likely to seek information." Seven years have established its reputation as a full and reliable safeguard and help. It should be in the possession of every insurance practitioner, and should "be brought to the notice of the younger men as they come into practice."

CO-OPERATION BETWEEN VOLUNTARY AND MUNICIPAL HOSPITALS.

IN the correspondence columns of the *Times* of April 10th Mr. Leonard L. Cohen, honorary secretary of King Edward's Hospital Fund for London, discusses some points in regard to the future of voluntary hospitals which were raised by Dr. C. E. S. Flemming in a letter published by that newspaper on April 6th. Referring to Section 13 of the Local Government Act, 1929, Mr. Cohen states that "the Special Committee of King Edward's Hospital Fund for London, appointed by H.R.H. the Prince of Wales, which is considering the relations between voluntary hospitals and municipal hospitals under the Act, is taking definite steps with a view to establishing an organization in the London area for the purpose of consultation with the London County Council. Immediate steps are also being taken by the British Hospitals Association to establish similar organizations outside London." The wording of Section 13 of the new Act is as follows: "The council of every county and county borough shall, when making provision for hospital accommodation in discharge of the functions transferred to them under this part of this Act, consult such committee or other body as they consider to represent both the governing bodies and the medical and surgical staffs of the voluntary hospitals providing services in or for the benefit of the county or county borough, as to the accommodation to be provided and as to the purposes for which it is to be used."

BRITISH CONGRESS OF OBSTETRICS AND GYNAECOLOGY.

THE seventh British Congress of Obstetrics and Gynaecology will be held in Dublin from April 24th to 26th, under the presidency of Dr. Gibbon FitzGibbon. The constituent societies are: the Sections of Obstetrics and Gynaecology of the Royal Society of Medicine and the Royal Academy of Medicine in Ireland; the Edinburgh Obstetrical Society; the N[illegible] Midland, and Glasgow Obstetrical and [illegible]; and the Ulster Medical Society. A discussion will be held on the management of cases of pelvic disproportion, and communications will be read on various gynaecological and obstetrical subjects. Among those who are contributing papers are Professor Polak of New York and Professor Adler of Vienna. In connexion with the congress an exhibition of pathological specimens is being arranged, and the congress dinner will be held on April 25th at the Royal College of Surgeons, St. Stephen's Green. The honorary secretaries are Dr. Bethel Solomons and Dr. Gerald Tierney.

GARTON PRIZE AND MEDAL.

THE Garton Prize and Medal has been instituted by the Grand Council of the British Empire Cancer Campaign with the object of promoting research into the nature, causes, prevention, and treatment of cancer. A medal, together with an honorarium of £500, will be awarded early in 1932 to the person or group of persons who shall submit the essay embodying the results of original investigations which, in the opinion of the judges appointed by the council, is the best contribution towards the early diagnosis of cancer. In the event of several dissertations of sufficient merit being submitted the prize may be divided or additional awards made. The prize will be reserved if no dissertation of sufficient merit is received. Candidates, who may be of either sex, must be British subjects domiciled in the British Empire or Dominions and not at the time members of the Grand Council of the Campaign. Dissertations must be printed or typewritten in English, and embody results of original investigations carried out, wholly or in part, during the three years immediately preceding the year in which the prize is awarded. They are to be delivered not later than December 31st, 1931. Further particulars may be obtained from the Secretary British Empire Cancer Campaign, 19, Berkeley Street London, W.1.

ETIOLOGY OF RHEUMATIC HEART DISEASE.

WE print in the *Supplement* this week (p. 93) an interim report on investigations into the etiology of rheumatic heart disease in the counties of Gloucester, Somerset, and Wilts, carried out under the auspices of the British Medical Association and the Medical Research Council. Although many replies were received by the committee, it is thought that other practitioners in this area may have under observation cases which answer to the definition given in the report, and the hope is expressed that these will send in clinical notes accordingly. The investigation will be continued until the beginning of October, 1930, when the data will be analysed and the final report published.

DEATH OF SIR ANTHONY BOWLBY.

WE have to announce with deep regret the death of Sir Anthony Bowlby, Bt., K.C.B., K.C.M.G., K.C.V.O. Honorary Surgeon to the King, Past-President of the Royal College of Surgeons of England, and consulting surgeon to St. Bartholomew's Hospital. Throughout the whole period of the war Sir Anthony Bowlby did invaluable work for the Army Medical Service as advisory consulting surgeon to H.M. Forces in France. A memoir, with portrait, will appear in our next issue.

SIR NORMAN WALKER will give an address on "Medical education and qualification in the United States" on Monday, April 22nd, at 5 p.m., in the Fore Hall of the University of Glasgow. The chair will be taken by Sir Donald MacAlister, Bt., Principal of the University and President of the General Medical Council.

THE British Orthopaedic Association has awarded the Robert Jones Medal and Association Prize for 1928 to Mr. E. P. Brockman for his essay on "Club-foot (congenital talipes equino-varus)."

SCIENTIFIC MEDICINE IN CHINA.

[FROM AN OCCASIONAL CORRESPONDENT.]

AMID all the political welter attending the effort of China to awake and show that she is a nation and not merely an anarchical combination of provinces, there are elements which indicate that she is really reviving. Returned students from Europe and America have been for years regarded as the curse of the country; they could not fit themselves in, and in many cases had an unsettling influence on all around them. But now that the Nationalist Government at Nanking has weathered various storms, and has been recognized by the Great Powers, there is more official stability than for many years past. Barristers, engineers, doctors, and other professional men are rallying and are combining to further collective progress. In the realm of medicine this progress is taking the form of the establishment of a ministry of health under a progressive lay official, Mr. Hsueh Tu-Pi, who while Minister of the Interior gave much encouragement to health work; his Vice-Minister is Dr. Liu Jui-Heng, a well-known surgeon from the staff of the Rockefeller College in Pekin. The new Ministry has already taken one important step by inviting Sir Arthur Newsholme and Drs. Rajchman and Victor G. Heiser to form an international advisory council to it.

Conditions in China are so different that a blind attempt to follow the health administrations of England, the United States, and Japan without any appreciation of underlying local principles would probably end in failure. However, they possess the many advantages of a late start, and the authorities are well alive to all the experiences we in England have gained since our public health work began in 1848.

Possible Lines of Development.

Consideration is being given, on as practical lines as possible, to the following proposals. (1) The registration of all medical schools, with full details of buildings equipment, number of students and teachers, and curricula. (2) The registration of medical graduates, and the guaranteeing of their accepting the ethics of the profession. (3) Formation of a general medical council from members of the leading medical schools and institutions. (4) Publication of an official medical register. (5) Publication of a Chinese pharmacopoeia. (6) Provision of a separate register of dentists, pharmacists, and nurses.

In Shanghai, where there are more than one hundred foreign doctors of all nations, who have set up in practice without producing credentials, the Chinese Commissioner of Health of Greater Shanghai is getting into touch with the British Commissioner of Health of the Foreign Municipality with a view to abolishing, by registration, the abuses now prevalent in the International Settlement. If this can be done in Shanghai, other treaty ports will follow suit, and the movement should spread to other large cities. Moreover, the indiscriminate sale of adulterated and impure drugs without the special trade marks and trade names of reputable firms is being taken in hand, as well as the charging of a high registration fee for secret remedies; efforts are being made to secure the adoption, in the case of imported drugs, of the same standard as in the country of origin.

Since the war ministries of health have been established in various countries, as, for example, in the kingdom of the Serbs, Croats, and Slovenes, and in Turkey. The success of these ministries has been due to their establishment of an administrative policy in conformity with modern medical knowledge and the actual needs of the country. Turkey has recently passed a law pertaining to patent medicines; sponsored by the ministers of hygiene, justice, and finance, it deals with all medicines sold, whether manufactured in Turkey or imported from abroad.

Medical Research.

As is well known, the twentieth century has seen Japan forging rapidly ahead in scientific medicine. Since Kitasato discovered *B. pestis*, Takamine, Noguchi, Hata, and many others have greatly contributed to the cause of research, and Japan's geographical proximity to China has not been without an emulative effect on the medical men of the latter country. Another incentive in this direction has emanated from the Pekin Union Medical College, which owes much to the munificence of John D. Rockefeller and also to his Foundation Trustees in New York; these have been careful to send out teachers of outstanding qualifications, such as Dr. Ten Broeck, a pathologist and bacteriologist, and Dr. J. B. Grant, professor of public health. Dr. Grant, who was born in China, has been at the back of community health work directed by Chinese medical officers of health working under the municipalities of different towns. The majority, probably all, of these doctors have specialized in public hygiene at Pekin, so that the movement which has been steadily spreading during the past half-dozen years is now finding its feet, and is on sound lines.

The Chinese people are unhampered by caste customs and prejudices; it is remarkable, as the writer well knows from experience, how the inhabitants of inland towns and villages will submit themselves to hypodermic injections of vaccines and antiserums in time of epidemics such as plague or diphtheria. China offers a wonderful field for research, riddled as it is by tuberculosis and parasitic diseases, many of which have, as yet, undiscovered extra-corporeal hosts.

Some Definite Achievements.

It may interest the profession at home to know some of the lines on which the medical world of Young China is at work.

Dr. M. Y. DZEN has been investigating the assertions, made by Zoeller and other workers, that in the yellow races the positive Dick test reactors, in scarlet fever, number only 8 per cent., a percentage which is much lower than that in the case of the white peoples. Reporting on a large number of cases, he found positive reactions in 46.4 per cent. of unselected persons, and the age relation resembled that of the incidence of scarlet fever. Two children who had a definite history of scarlet fever respectively one and four years previously showed strong positive Dick reactions.

Dr. Zau Zung-Daw has been working on the intravenous injection of calcium chloride in the treatment of acute epididymitis, which occurs as a complication in about 25 per cent. of cases of posterior gonorrhoeal urethritis. The pain of epididymitis is intense, and the rapidly destructive process frequently ends with obliteration of the tubules or vas deferens, with azoospermia and sterility. Treatment to be of any use must be early and effective. Dr. Zau's results in sixty-five cases indicate that the intravenous injection of calcium chloride is a safe procedure, provided that care is taken to avoid extravasation of the solution into the perivascular tissue. It is also efficacious in the treatment of acute prostatitis and arthritis. The almost instant arrest of the process following the injection renders this treatment especially desirable, and it has the advantage over other forms that the patient need not be kept in bed, so that its safety and efficacy would seem to justify its more extensive use.

There is at Pekin a National Epidemic Prevention Bureau from the laboratories of which a large number of vaccines and antiserums are sent all over the country. Dr. E. T. H. Tsen is the director, and is most assiduous in the collection of reports as to the action of the bureau's products. Rabies is widespread in China, and the deaths from it are tragically dramatic. Since 1923 Dr. Tsen has been preparing and issuing phenolized rabies vaccine, which remains potent for four months, so that it can be dispatched long distances to remote provinces. In 1928 there were sent out 252 sets of this vaccine, and only one death followed its use. All this spells progress.

In the north, in Manchuria, Dr. Wu Lien-Teh, director of the plague service, has with his staff continued his researches into the epidemiology of plague, which in that region usually tends to assume the pneumonic form. Dr. Wu is also editor of the *National Medical Journal of China*, which is the organ of the unofficial National Medical Association and never lacks contributors, most of whose articles are written in excellent English.

It is interesting from the foregoing to note the spread of modern medicine in this ancient country, which has written records of a civilization dating from 1,500 years before the Christian era. One can often read of the Westernization of the Far East and the introduction to it of our civilization, but much of this is materialistic, the outcome of a mechanical age. Empiric medicine has long held sway in China, and while there are points in its favour, it has been practised by ignorant natives, too often with disastrous results to their patients.

The steady growth of medical science and investigation by educated foreign-trained Chinese graduates is a feature that merits the encouragement, the deeper interest, and the helping hand of our own well-ordered profession.

MEDICAL SCHOOLS AND HOSPITALS.

AN AUSTRALIAN SURVEY.

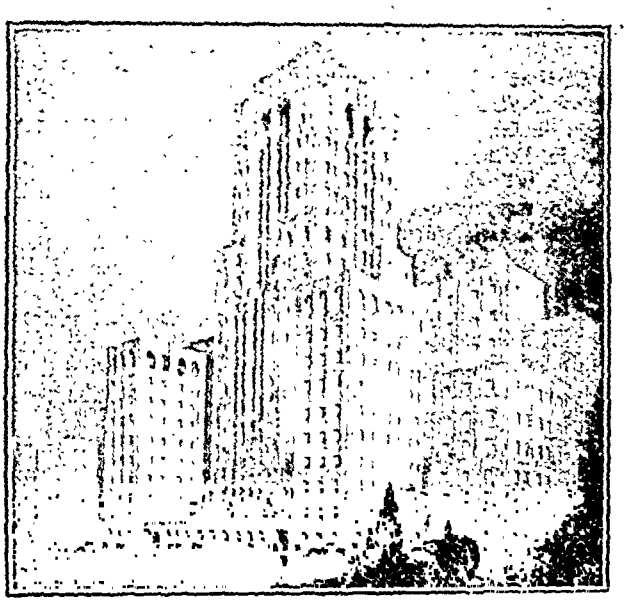
DURING the past two or three years there has been much questioning in the State of Victoria on the future of the Melbourne Medical School and its relation to the hospitals for clinical instruction. We reviewed in our issue of November 12th, 1927 (p. 892), a report of three representatives of the State who had been sent upon a mission of inquiry to the United States of America and Canada to investigate related conditions in those countries. This report has now been issued for general information, and there is bound up with it a further report by Professor R. J. A. Berry,[1] who formerly held the chair of anatomy in the University of Melbourne, and who was a member of the mission of inquiry.

He states that the war impressed upon all medical administrators the necessity for co-operation, the great value of the research hospital, and the vital importance of the medical centre devoted to community health. Yet in Melbourne to-day he finds a medical position that is the product and relic of mid-Victorian ideas. Medical education is carried out in a medical school that is detached from the clinical hospitals, and the several departments of the school are unrelated. The University has no control, direct or indirect, on the clinical hospitals; these have no common objective, and merely function as isolated and competitive units.

During his tour Professor Berry investigated 21 of the leading university medical schools of Canada, the United States, and Great Britain, and some 115 institutions and hospitals. He gives a lucid and vivacious account of his observations. He maintains that everywhere he finds a change in the ideas that inspire hospital treatment and medical education. The objective of all medical effort is the patient. This conception demands unity of purpose, concentration of effort, and a constant investigation of the laws of health as well as the processes of disease. It is now universally recognized that medical research is an integral part of medical treatment, and consequently the modern idea requires the concentration on the one spot of all branches of medicine.

The examples Professor Berry gives of the vast equipment of certain of the Canadian and American medical centres are enough to arouse envy in the heart of many readers. But despite economic adversity, which he says is delaying advance in these islands, he finds concentration schemes in being in Aberdeen and Birmingham, and developments of pathological departments in the older universities of Oxford and Cambridge, which are practical proof of the community spirit in medicine. A change, also, he finds in building arrangements; there is concentration rather than dispersion. Instead of spreading the hospital building over a vast area the tendency in America is to build it up into the sky, and a picture (reproduced herewith) is given of the New York State Psychiatric Institute and Hospital, which shows that it vies with the sky-scrapers. He indicates that this is not a mere fashion, but the expression of a real purpose. Hospital and school of medical and allied sciences are brought together in the one building.

"Anatomists and physiologists, pathologists and research fellows generally, may walk from their laboratories into the wards. The clinicians have all the medical scientific departments absolutely at hand, which means that the full resources of medicine are at the service of every patient, irrespective of his means. Such a combination is stimulating in the highest degree to every medical officer in the associated departments, whilst the benefits to the patient are incalculable, and cannot be attained in their entirety in any other way."



New York State Psychiatric Institute and Hospital.

Professor Berry has something to say on hospital policy. Brought up in this country, where the voluntary hospital is the pivot of hospital work, he finds other methods elsewhere which he believes to be better. He suggests that it is a mistake to look upon the hospital as a place for the treatment of the poor. He prefers the American practice, based upon the idea that a hospital should be for all.

"American medical and hospital administrators have clearly recognized the justice of this contention. It is to-day the bounden duty of medicine to give every type of patient access to its hospitals, for only there can medicine give its best; but the labourer is worthy of his hire, and it is illogical in the extreme to suppose that, because the British type of voluntary hospital was based on gratuitous service by all concerned, that this more modern duty of medicine can be maintained on the same basis. In other words, if all classes of patients are to be admitted to our great hospitals, then the medical staff must be paid for their services. It is to the credit of the Americans that they have not only recognized the truth of this principle, but have had the courage to put it into practice, and in every one of the great university hospitals visited by me in Canada and the United States I found every member of the staff of both medical school and hospital was paid, and well paid, for their services."

His opinion, based on personal observation, is that under the new methods "the hospitals become self-supporting and entirely free from that bureaucratic control feared by the more ardent supporters of the British voluntary system." He quotes the revenue of a Canadian medical centre at Toronto for 1926. The income received was as follows:

	£
Receipts from patients	148,875
Endowments and subscriptions	16,075
Miscellaneous receipts	3,030
Allowances from the city of Toronto for indigent patients	22,300
Allowances from province of Ontario	15,749
Allowance from outside townships	4,621
From Federal and Provincial Governments for the treatment of venereal disease	2,300
	£213,000

This sum covered the attendance of 65,136 out-patients and 12,698 in-patients.

The problem before the Faculty of Medicine in Melbourne has been defined by Professor Berry in a letter published in the *British Medical Journal* of November 26th, 1927: "The Melbourne problem is, then, that which now everywhere confronts medicine: the seeking of the best combination of research, teaching, hospital, and laboratory in the cause of the national health—that is, the elimination of disease by study, research, and co-operative effort."

[1] *Report on the Hospital-Medical School Problems of the State of Victoria.* By Professor R. J. A. Berry, M.D. Melbourne, Victoria: H. J. Green, Government Printer. 1928. Pp. 39. Price 1s. 6d.

Nova et Vetera.

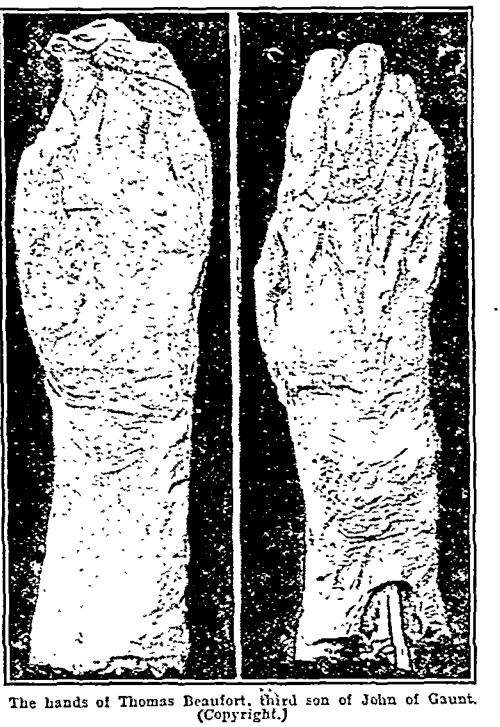
THE HANDS OF THOMAS BEAUFORT, THIRD SON OF JOHN OF GAUNT.

AMONG the relics of historical interest in the Museum of the Royal College of Surgeons are two hands, said to be those of Thomas Beaufort, the third son of John of Gaunt, Duke of Lancaster, who died in 1427. The strange story of how they were discovered and came to be preserved in the Museum is one of more than ordinary interest.

Thomas Beaufort was the third son of John of Gaunt by his third wife, Lady Catherine Swynford. He won fame as a soldier and also held distinguished offices under the Crown during the fifteenth century. He was half-brother to Henry IV, and was created Earl of Dorset, Duke of Exeter, and Knight of the Garter. In 1407 he was made captain of Calais, and shortly after was appointed admiral of the northern and western seas for life, and on the accession of Henry V was made lieutenant of Aquitaine.

In 1415 he accompanied Henry V on the invasion of France, commanded the rearguard at the battle of Agincourt, and took part in other important engagements. He captured Evreux, showing great courage and bravery, was prominent at the siege of Rouen, and was eventually made captain of that city. After a long campaign in the coast towns of Normandy he returned to England upon the death of Henry V in 1422, and jointly with his brother Henry, Cardinal Bishop of Winchester, was appointed by Parliament to take charge of the royal infant Henry VI.

Thomas Beaufort died at his Manor of Greenwich at the age of 52, on January 1st, 1427, and by his will (given in Dugdale) he directed that he should be buried in the Abbey of St. Edmund's Bury, near his wife, who had predeceased him, at the entrance to the Chapel of Our Lady, close to the wall. Here, according to the record, his body was found 350 years later, "as perfect and entire as at the time of his death."



The hands of Thomas Beaufort, third son of John of Gaunt. (Copyright.)

The next part of the story, which tells of the discovery of the body, is related in a communication made to the Royal Society by Dr. Charles Collignon, professor of anatomy at Cambridge, on June 25th, 1772. It is entitled "Some account of a body lately found in uncommon Preservation under the Ruins of the Abbey at St. Edmund's Bury, Suffolk, with some reflections on the subject." The professor states that,

"In the month of February last, some workmen, digging among the ruins of this Abbey, discovered a leaden coffin supposed from some circumstances to contain the remains of Thomas Beaufort, Duke of Exeter.

"As it certainly was buried before the dissolution of the Abbey, it must have been there two or three hundred years. It was found near the wall on the left-hand side of the Choir of the Chapel of the Blessed Virgin, not enclosed in a vault, but covered over with common earth. Mr. Thomas Cullum, a surgeon, says the body was enclosed in a leaden coffin surrounding it very close, so that you might easily distinguish the head and feet. It was wrapped round with two or three large layers of cere-cloth, so exactly applied to the parts that the piece which covered the face retained the exact impression of the eyes and nose."

After giving an account of the internal organs as he found them, the professor observes that

"the hands retain the nails, and the cere-cloth, which was of considerable weight, was doubtless put on hot. Might not the cere-cloth, impregnated perhaps with gums or resins, thus excluding the air, have accounted for the preservation of the body?"

Cere-cloth, in which the bodies of the dead were often wrapped before burial during the Middle Ages, was a coarsely woven material prepared by dipping it into melted wax, that had been impregnated with myrrh, cinnamon, and other preservative spices. Fabyan, in 1494, alludes to "Ye corps to be seryd and anoynted with ryche and precyose bawmys," and Murray gives the following quotation from a work printed in 1557: "Ceere them [the bodies] in three score foldo of ceered cloths."

It was not until the middle of the last century that further light was thrown on the subject, by the discovery of a manuscript purporting to have been written by one Joseph Pater of Bury St. Edmunds, at the time when the remains were found. According to this document:

"On the 20th of February, 1772, some labourers employed in breaking up part of the old abbey church discovered a leaden coffin which contained an embalmed body as perfect as at the time of its death; the features and lineaments of the face were perfect, which were covered with a mask of embalming materials. The very colour of the eyes distinguishable; the hairs of the head brown, intermixed with some grey ones; the nails fast upon the fingers and toes as when living; stature of the body about six feet tall and genteelly formed.

"The labourers, for the sake of the lead (which they sold to Mr. Faye, plummer in this town, for about 15s.), stript the body of its coffin and threw it promiscuously amongst the rubbish. From the place of its interment it was soon found to be the remains of Thomas Beaufort, third son of John of Gaunt, Duke of Lancaster.

"He was a great benefactor to this church, died at East Greenwich in 1427, in the 5th year of King Henry ye Sixth, and was interred in this Abbey near his duchess as he had by his will directed. On the 24th of February following, the mangled remains were enclosed in an oak coffin and buried about eight feet deep, close to the north side of the north-east pillar which formerly assisted to support the Abbey belfry."

The writer concludes by stating:

"Before its re-interment the body was mangled and cut . . . by Thomas Gery Cullum, a young surgeon in this town. The skull he sawed in pieces . . . his arms chopped off below the elbows and taken away. The crucifix, supposed to be a very valuable one, is missing. It is believed the body of the Duchess was found (within about a foot of the Duke's) on the 24th of February.

"Every sensible and humane mind reflects with horror at the shocking and wanton inhumanity with which the princely remains of the grandson of the victorious King Edward the Third have been treated and 345 years after his death.

"One of the arms the said Cullum confesses to have in spirits."

This account corresponds to some extent to that given by Professor Collignon, who had evidently been informed of the circumstances by Mr. Cullum.

Thomas Ghery Cullum, the surgeon mentioned in the manuscript and also by the professor, was the younger son of a Suffolk baronet of that name, and on the death of his brother succeeded to the title and relinquished medical practice. Apparently he kept one of the hands he had sawn off and for a time the other disappeared, but, according to Jeaffreson, it came into the possession of a showman, who exhibited it about the country at the fairs he visited. It eventually became the property of John Hunter, who may have bought it from the showman, for it found a place in his great anatomical collection and was among the specimens in his museum when the former was purchased by the Government after Hunter's death in 1793. The other hand, which had been retained by Sir Thomas Ghery Cullum, was presented by him to the College of Surgeons in 1814. In this curious way the two

hands of Thomas Beaufort, after being separated for forty-two years, came together again.

The hands even now, after a period of five hundred years, are in a remarkable state of preservation. They have apparently been kept with care, and are finely formed with long tapering fingers and small nails (now missing).

The total length of the right hand taken from the back is 10½ inches (26.55 cm.), and the length of the hand alone, measuring from the line joining the styloid process of the ulna and radius to the tip of the middle finger, $7\frac{5}{16}$ inches (18.55 cm.). The diameter from median to lateral metacarpal is $2\frac{3}{4}$ inches (7 cm.). Allowing for shrinkage in the process of time, the hands are below the average in size for a man. It is noticeable, however, that the wrists are strong and well knit, as might be expected in those of a good swordsman and great warrior such as Thomas Beaufort, Duke of Exeter.

Thanks are due to the Conservator, Sir Arthur Keith, for kind permission to reproduce the photograph of the hands taken by Mr. Stewart.

C. J. S. Thompson, M.B.E.

MEDICAL MEMBERS OF LOCAL PUBLIC BODIES.

SCOTLAND.

In reply to a request made in the *British Medical Journal* last year for the names of medical practitioners who are members of local authorities or their subsidiary public bodies in Great Britain many replies were received, and lists of names were published on December 8th, 1923 (p. 1057), December 29th (p. 1190), and February 16th (p. 314). The information thus received related principally to England and Wales, only a few names being reported from Scottish authorities. Further details have since been received in this last respect, and it is now possible to publish a more complete list of names. Special interest attaches to it in view of the pending disappearance of education authorities and parish councils, their duties being taken over by county councils and the town councils of the larger boroughs.

County Councils.

Argyll.—Dr. J. C. Boyd, Dunoon.
Bute.—Dr. J. H. Paul, Millport.
Clackmannan.—Dr. E. E. Dyer.
East Lothian.—Dr. W. C. McEwan, Prestonpans.
Inverness.—Major A. D. Mackinnon, C.M.G., Kyleakin, Skye.
Lanark.—Dr. John Reid, Forth; Dr. J. Rogerson, Dalserf.
Midlothian.—Dr. W. Young, West Calder.
Orkney.—Dr. W. A. Sinclair, Kirkwall.
Peebles.—Dr. J. R. Jeffrey.
Renfrew.—Dr. J. M. Smeaton, Barrhead.
Ross and Cromarty.—Dr. D. J. Macrae, Lochalsh.
West Lothian.—Dr. J. Keay, Bangour; Dr. A. S. Kelso, Broxburn; Dr. S. G. Ogilvy, Fauldhouse.
Wigtownshire.—Dr. D. Matthews, Glenluce; Dr. E. Shaw, Wigtown.

Town Councils.

Arbroath.—Dr. W. J. Dewar.
Ayr.—Dr. A. A. Young.
Banff.—Dr. J. H. Stephen.
Berrie.—Dr. Chas. Aymer.
Buckie.—Dr. G. Hendry.
Burghead.—Dr. W. D. Sutherland.
Dumfries.—Dr. G. R. Livingstone.
Dunoon.—Dr. J. W. Hill.
Edinburgh.—Dr. T. G. Nasmyth; Dr. G. F. Barbour Simpson.
Ellon.—Dr. W. Sinclair.
Forfar.—Dr. J. A. Lowson (Provost).
Fort William.—Dr. T. L. Brander.
Glasgow.—Dr. Jas. Dunlop, Shettleston; Dr. Jas. Dunlop, Dennistoun; Dr. R. Forgan; Dr. S. H. Bennett.
Jedburgh.—Dr. J. Hamilton Hume.
Kelso.—Dr. A. D. Fleming.
Kingussie.—Dr. F. Savy.
Kintore.—Dr. H. R. Vernon.
Kirkintilloch.—Dr. A. D. Cowan.
Laurencekirk.—Dr. J. C. M. Matheson.
Leslie.—Dr. A. R. Wight (Provost).
Lockerbie.—Dr. G. H. Sinclair.
Maybole.—Dr. W. P. Sandilands.
New Galloway.—Dr. J. Cowan (Provost).
Paisley.—Dr. W. H. Gibson.
Sanquhar.—Dr. J. K. Dunlop.
Stonehaven.—Dr. Chas. Burns (Provost).
Tain.—Dr. E. K. Mackenzie.
Thurso.—Dr. A. Asher (Provost).
Whithorn.—Dr. J. G. McWhirter.
Wigtown.—Dr. E. Shaw (Provost); Dr. W. Lilico.

Parish Councils.

Cleland (Lanarkshire).—Dr. A. Wright, Salsburgh.
Cromdale (Morayshire).—Dr. W. H. M. Barclay, Grantown-on-Spey.
Dallas (Morayshire).—Dr. R. Douglas, Elgin.
Kilchoman (Argyllshire).—Dr. D. MacLachlan, Islay.
Tain (Ross-shire).—Dr. E. K. Mackenzie, Tain.
Yetholm (Roxburghshire).—Dr. A. Rodger, Yetholm.

Education Authorities.

Aberdeenshire.—Dr. A. Hendry, Ballater.
Ayrshire.—Dr. W. P. Sandilands, Maybole.
Berwickshire.—Dr. J. Cairns, Duns; Dr. F. O. Taylor, Coldingham.
Caithness.—Dr. A. Asher, Thurso; Dr. J. R. Kennedy, Dunbeath.
Dumfriesshire.—Dr. W. Park, Moffat.
East Lothian.—Dr. D. R. Macdonald (Chairman).
Fifeshire.—Dr. E. E. Morrison, St. Andrews.
Kincardineshire.—Dr. W. Sinclair, Nigg.
Midlothian.—Dr. W. Young, West Calder.
Morayshire.—Dr. T. H. W. Alexander, Elgin; Dr. J. Bruce, Forres.
Orkney.—Dr. Wm. Park, Kirkwall.
Perthshire.—Dr. G. F. Barbour, Pitlochry; Dr. R. Stirling, Perth.
Ross and Cromarty.—Dr. J. Broadfoot, Dingwall; Dr. D. Johnstone, Cromarty; Dr. D. Wallace, Ullapool.
Selkirkshire.—Dr. E. M. Tyrrell, Galashiels.
Stirlingshire.—Dr. C. E. Blair, Kilsyth.
Sutherlandshire.—Dr. E. A. C. Beard, Armadale; Dr. J. D. MacRae, Bonar Bridge.
West Lothian.—Dr. Wm. Anderson, Armadale.
Wigtownshire.—Dr. D. Matthews, Glenluce; Dr. E. Shaw, Wigtown.
Edinburgh (Burgh).—Dr. W. G. Sym.

BRITISH EMPIRE CANCER CAMPAIGN.

The Marquess of Reading presided at the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held on April 8th, when the following grants were made: £3,500 to the Cancer Research Department of the Middlesex Hospital, £650 for cancer research work at St. Mark's Hospital, London, £80 for cancer research work being carried out by Dr. J. C. Mottram at the London Radium Institute; and a sum of £50 for special investigations to be made at the Cancer Hospital, London, under a scheme submitted by Dr. E. L. Kennaway.

The newly formed Cancer Research Centre in the North of Ireland was invited to become an affiliated body of the Campaign, and congratulations were extended to the recently organized New Zealand Branch of the Campaign, which was inaugurated during the visit to Wellington by Mr. W. Sampson Handley. It was reported that the New Zealand Branch had been established under the patronage of the Governor-General and a representative committee has been appointed, the Prime Minister of the Dominion having promised Government support for the movement.

A summary of the recommendations made by the Committee of the International Conference, held last July, was submitted and the Council passed the recommendations to the Investigation Committee of the Campaign to take action in initiating executive action on the proposals. The report makes important suggestions for the continued investigations upon many lines of work reported on at the conference, and the committee stresses the necessity for the institution of standardized records of results of patients treated by radium and x rays. It urges that the British Empire Cancer Campaign, in collaboration with the Medical Research Council and the Ministry of Health, should invite all institutions using radium and x rays to utilize an agreed form of record.

The Council received the final reports on the subject of the Garton Prize and Medal for promoting investigations into the nature, causes, prevention, and treatment of cancer, to which reference is made elsewhere this week (p. 698).

It was announced that the midsummer ball would be held on June 5th this year, under the patronage of the Duke and Duchess of York and the presidentship of Lord and Lady Reading, and that Lady Bland-Sutton had undertaken the chairmanship of the Ball Committee.

England and Wales.

Dinner to Lord Moynihan.

THE University of London Medical Graduates Society will give a complimentary dinner to Lord and Lady Moynihan of Leeds at the Hotel Metropole, King Street, Leeds, on Friday, April 19th, at 7.15 for 7.30 p.m. The chair will be taken by the president, Sir StClair Thomson. Any medical graduates of the University of London who desire to be present should apply at once to Dr. Rhoda Adamson, 24, Park Square, Leeds, who is acting as local honorary secretary. The price of the dinner will be half a guinea (exclusive of wines), which should be sent with the application for a dinner ticket.

Public Cleansing in London.

The report of an Investigation into the Public Cleansing Service in the Administrative County of London, by Mr. J. C. Dawes, has lately been issued.[1] This report, made on the instructions of the Minister of Health, gives for the first time a clear and exhaustive account of the public cleansing service of London, by which it is to be understood the arrangements for dealing with the huge quantities of house and other refuse which have to be collected in the metropolitan area, the cleansing of streets, and the many ancillary services. The great sanitary and economic problems which this service presents are examined in detail, and special consideration is given to the refuse dumps which disfigure some districts outside the metropolis. Mr. Dawes alone is responsible for the report and for the opinions expressed therein. It contains a large number of facts and many illustrations, and a number of tables giving details of this important sanitary service. Of special interest to those responsible for the local government of London are the conclusions at which Mr. Dawes has arrived as the result of his investigation, and his suggestions for the future organization of public cleansing work in London. He is of opinion that, from the technical standpoint, the existing system under which there are twenty-nine separate cleansing authorities for London has not proved a success, and that a satisfactory service for what is really one compact area can be provided only by centralized arrangements under a special body representative of all the sanitary authorities. He considers also that it would be well that some, at any rate, of the districts outside the metropolis should be included in any joint scheme that may be devised. As regards the present service, Mr. Dawes finds that the arrangements for refuse collection are defective in important respects—for instance, the scattering of dust during loading, and the use of vehicles of obsolete design. Some methods of disposal come in for severe criticism, the practice of indiscriminate dumping in particular being strongly condemned. It is stated in the foreword that any proposals on the lines suggested in the report for centralizing this service need to be considered in the light of the prevailing organization of local government, and also in relation to other services, and that the Minister has decided to appoint a representative committee to consider the question of giving effect to the report. Further reference to this important document will appear in an early issue of the *Journal*.

Ancoats Hospital, Manchester.

When Ancoats Hospital was founded in 1828 the institution was more aptly designated a "dispensary." In the hundred years that have elapsed there have been many changes in the clinical organization of this institution, consequent on increasing size and closer association with the university; structural additions were made in 1888, 1900, 1915, and 1921. In view of its centenary special reference is made to this expansion and the future possibilities in the current annual report of the medical board, of which Mr. Arnold Renshaw is chairman. Good results have followed the establishment of a new out-patient clinic in genito-urinary surgery, and a cancer clinic is now available for the study of inoperable cases and new methods of treatment. Owing to the long waiting list it is only possible to admit the more serious cases to the wards; this necessitates many minor operations being performed in the out-patient department. The chairman comments on the valuable educational facilities made available by Ancoats Hospital, and expresses the hope that in future it will take a still greater share in undergraduate and post-graduate study. He looks forward to the time when there will be a larger proportion of graduates from the Manchester medical school holding resident appointments or associating themselves otherwise with the clinical work of the hospital. He comments finally on the greater burden which the coming extension of the scope of the municipal health services will place upon the voluntary hospitals, requiring them to devote themselves more intensively to specialization in research and treatment.

[1] H.M. Stationery Office, price 15s.

Treloar Cripples' Hospital, Alton.

On April 5th the trustees of the Lord Mayor Treloar Cripples' Hospital and College entertained members of the honorary medical board at dinner to meet the Lord Mayor and Sheriffs of London. The dinner was held, by permission of the Master and Wardens of the Barbers' Company, at Barbers' Hall, in Monkwell Street. Lieut.-Colonel Frederick Lawson was in the chair, and the other trustees present were the Lord Mayor, Miss Florence Treloar, and Mr. T. J. Harrowing. The speeches included many tributes to the pioneer work by Sir William Treloar for crippled children, to the hospitality of the Barbers' Company and its former associations with surgery, and to the inspiring enthusiasm of Sir Henry Gauvain, medical superintendent of the Hospital and College at Alton. The toast of "The Lord Mayor and Corporation of the City of London" was submitted by Sir Alfred Robbins, and responded to by the Lord Mayor, Sir Kynaston Studd. In proposing "The health of the honorary medical board," the chairman said that this was the twenty-first anniversary of the foundation of the hospital, and that during its existence 5,000 patients had been cared for with a mortality of only 2 per cent.; in 95 per cent. of cases surgical tuberculosis had been arrested at Alton. Mr. O. L. Addison, chairman of the executive committee of the honorary medical board, in his reply, spoke of the revolution in the out-patient surgical departments of children's hospitals in recent years, thanks to the work of the Treloar Hospital and its example. Sir James Berry, in proposing "The health of the trustees," contrasted the treatment of hip disease nowadays with the pitiable state of affairs fifty years ago, when he was a surgical dresser at Bart's. Mr. Leonard Denny (Master of the Barbers' Company), at the request of the chairman, pointed out, one by one, some of the treasures preserved in the Hall, which was built in 1640 by Inigo Jones on the site of a much earlier Barber-Surgeons' Hall. Holbein's famous picture of Henry VIII granting his Charter to the Barbers and Surgeons was in full view of all; and the Master showed the cup given by Henry VIII, and other pieces of priceless plate.

Scotland.

Maternal Mortality work in Edinburgh.

THE annual meeting of the Edinburgh Hospital for Women and Children and the Elsie Inglis Memorial Hospital was held at Edinburgh on March 21st. Mrs. Chalmers Watson, C.B.E., M.D., presided. It was stated that the ordinary income for the year amounted to £11,466, which showed a slight increase over that of the previous year, while the expenditure had increased to £12,866. Dr. J. Parlane Kinloch of the Scottish Department of Health said that those working in the hospital were engaged on the central problem of their national health. Out of every 1,000 births each year in Scotland seven women died, and the greater part of that maternal mortality was preventable. These figures did not take into account the great mass of disablement and disease which was experienced by the mothers who survived. The hospital was making a beginning with the work, and that work would extend. He stated that there were three ways of preventing maternal mortality. T[illegible]preventive midwifery, an

increasingly adequate midwifery nursing service, and better medical research into some of the problems on which they were working.

Physical Defectives in Glasgow Schools.

At a meeting of Glasgow Education Committee on April 4th, a report was presented by the authority's medical officer and the visiting surgeon to the Royal Hospital for Sick Children, dealing with orthopaedic cases examined by them in the schools for physical defectives. The report stated that 164 children suffering from various defects and deformities had been examined, and that all of these required continuous supervision during the whole of their school life in order to correct or prevent deformities. None of the cases required residence in hospital for more than two or three weeks at a time, and the opinion was expressed that closer co-operation between hospitals, patients, and parents would prove of permanent benefit to the children. It was agreed at the same meeting to appoint a special committee in view of the reports received from the Scottish Department of Health indicating marked improvement in the health and physique of school children who had received an addition of milk to their ordinary diet. A member of the Education Authority stated that it had been calculated that the supply of half a pint of milk daily throughout the children's school life would result in an increase of four inches in height and of fifteen pounds in weight. The authority's powers were, however, limited, and food could be given only to necessitous children. It was suggested that school milk clubs should be formed to enable the children to defray the cost of this extra milk, which would amount to fourpence a week for each child, and arrangements were made for experts to address the teachers and scholars on the subject.

East Fortune Sanatorium.

The sixth annual report of the East Fortune Sanatorium for Tuberculosis has just been issued. This sanatorium is maintained jointly by the south-eastern counties of Scotland for cases of tuberculosis occurring within their area. During the year 1928, 113 cases of lung disease were admitted, of which 86, or 76 per cent., had the disease in an advanced stage, while only one patient could be regarded as an early case. Thirty-nine patients were admitted suffering from disease of the bones, joints, and abdomen, and of these 20, or 51 per cent., had disease of an advanced type, while in only 3 could the disease be regarded as in an early stage. The advanced stage of the disease naturally necessitated long periods of residence. The number of admissions had, however, been decreasing for the last three years, in which the figures had been respectively 284, 218, and 193, while the number of discharges had similarly fallen, the figures being 252, 187, and 165. The numbers in residence, however, remained approximately the same on account of the lengthening in the average period of residence. While in 1926 the average period of residence of those discharged during the year was 197 days, in 1928 the average term of residence had risen to 472 days.

Scottish Blind Women.

The Thomas Burns Home for Blind Women, Alfred Place, Edinburgh, was opened on March 26th by the Countess of Haddington. The Rev. Thomas Burns, chairman of the directors of the Edinburgh Royal Blind Asylum and School, said that the institution's first home for blind women was on a small scale, and was opened in 1825 in the buildings of the institution at the south corner of Hill Street and Nicolson Street, and this had served its purpose for fifty years. When the West Craigmillar buildings were opened in 1876, part of these buildings were set aside for use as a women's home, but the directors had decided, more than ten years ago, to provide a separate and larger home. In November, 1926, an anonymous gift of £1,000 for a new home was received by the directors, and this was followed by several other donations of considerable amounts. The new home provided accommodation for sixty women, and forty-two were now in residence. The total cost, which included furnishings and the laying out of the grounds, was £18,500, of which approximately £7,600 had been provided by the local authorities and the State. Sir Leslie Mackenzie said that for a generation Dr. Burns had been a personality in the city life of Edinburgh. He had made it his special task that the problem of the blind in Scotland should be solved on Scottish lines. He considered that Dr. Burns deserved the honour of having the institution named after him, and he wished also to pay a tribute to the interest taken by the local authorities and the civil service in the treatment of the blind. A large portrait of Dr. Burns was presented to the home.

Falkirk Infirmary.

At the annual meeting of subscribers to Falkirk and District Infirmary it was reported that the ordinary income for the past year had amounted to £9,569, an increase over that of the previous year of £354, while the total expenditure for the year had been £7,637, or £336 less than in 1927. Dr. John Young, chairman of the board of managers, presided, and made a statement with regard to the progress that was being made in relation to the provision of the new infirmary for East Stirlingshire. The net amount raised for this purpose up to December 31st, 1928, had been £54,427, and accordingly operations in connexion with the erection of a first section of the new infirmary had been undertaken, and early completion was expected. The chairman further stated that in the new infirmary provision was to be made on a modified scale for the reception of paying patients, and the experiment of this policy would be looked forward to with interest.

Ireland.

A New Hospital for County Armagh.

A LETTER has been addressed by the Ministry of Home Affairs, Northern Ireland, to the Armagh County Council, in which the Minister stated that as the present county infirmary building was out of date and the surroundings unsuitable, it was thought inadvisable to spend money on alterations, but that a new building would be a more economical proposition eventually. The question was not one of so many more beds, as presumably sixty would be sufficient—unless child welfare and maternity, etc., were to be added; but there must be better accommodation for the *x*-ray department, on which over £600 had been spent; for the house-surgeon, who used the boardroom at present; for the matron and nurses, who had now no place to retire when off duty; and for the extern department. With regard to the last-named, there was only seating accommodation in the entrance passage for about six people, and even then there was inconvenient crowding. A proper operating theatre was required and a separate place for accident cases. If the surgeon's residence were used for some of these purposes a new house would have to be built for him in the yard, as the ground at the back fell away steeply from the buildings. With regard to district hospitals, the existence of these would not do away with the necessity for the skilled treatment of serious surgical cases in the county infirmary. Of course, these could be treated in Belfast, but probably they could be as efficiently and more conveniently treated in the county infirmary if a modern building were erected. The county council contributes £3,000 per annum to the present institution. Under the Local Government Act (Northern Ireland), 1923, there appears to be power to erect a county infirmary on a new site and to expend on it "such sum as the Council think fit."

Medical Certification of Insured Persons in the Irish Free State.

The National Health Commission, in a letter addressed to medical certifiers, has referred to its circular letters of September 15th and December 14th last on the subject of the proposed alteration of the basis for the distribution of the funds available for medical certification. Following an interview between the Minister for Local Government and Public Health and representatives of the medical profession, it has been decided to postpone the introduction of the proposed change from the dispensary to the county basis pending further consideration by the Minister of

questions concerning national health insurance as a whole. After consultation with the Minister for Finance, the Commission has, however, decided that the extra cost of administration entailed by the retention in certain certification areas of the dispensary district as the unit of distribution of the Medical Certification Fund cannot be allowed to remain a charge on State Funds. The amount involved—namely, £800 per annum—will, therefore, without prejudice to the larger question which awaits the Minister's decision, be deducted meanwhile from the moneys made available for medical certification. As, however, the county boroughs and urban districts of over 10,000 inhabitants have not been affected by the Commissioners' proposals, it is not intended to charge any of the £800 against the moneys applicable to these areas, but to recover the entire amount from areas outside the county boroughs and urban districts referred to. This will mean a reduction this year of 2.65 per cent. approximately in the respective dispensary pools. The Commission states that it is proposed to bring this arrangement into operation as from January 1st, 1929.

Correspondence.

COLLES'S FRACTURE.

SIR,—There are a few points in the discussion on this subject to which I think it necessary to refer. One writer objects to the method of reduction practised by Sir Robert Jones. This must be the method he and I learnt from our lamented friend Mr. Hugh Owen Thomas, which is simple, successful, and, moreover, requires no anaesthetic. The pain of reduction lasts only a few seconds, and its disappearance is followed by complete relief. I had the privilege of demonstrating this mode of reduction at the Royal Society of Medicine (Surgical Section, November 8th, 1910) during a paper by Sir Robert Jones on fractures in the neighbourhood of joints, which was published in the *Proceedings* of December, 1910, with reference also to the *Proceedings* of 1908 (Surgical Section, p. 221).

One of the difficulties in the treatment of Colles's fracture is to prevent return of deformity even after skilful reduction. This is best effected by using splints of sheet metal, twisted in the direction of pronation and lipped at the lower end, so as to catch the hand and lower fragment of the radius in the one case, and the lower end of the ulna in the other. At the very beginning of his own use of the "twisted splints" in Colles's fracture in this way Mr. H. O. Thomas put up my own forearm in them, with the effect of at once preventing supination and further pronation and producing a feeling of security. This is the greatest advance in the splinting of Colles's fracture. The bandaging must, however, be quite slack, and to keep the splints from slipping my practice has been to apply sticking-plaster, folded with the sticky side out, between the padded splint and the forearm. Otherwise union in the fracture may be delayed by the "anaemia of pressure." This precaution of avoiding tight bandaging was a constant principle in Mr. H. O. Thomas's practice, and his care, skill, and judgement can be known only to those who saw him at work. Along with this slack bandaging the forearm may be allowed to hang without sling, as some swelling is no detriment, but permits nutritive juices to pervade the seat of fracture and hasten union.

The only "impaction" that can occur is the unreduced rotation of the lower radial fragment, producing pain by the abnormal stretching of the extensor tendons in the rotated and displaced fragment. The absence of real impaction was explained by the late Professor Gordon of Belfast in his *Treatise on Fractures of the Lower End of the Radius* (Churchill, 1875), where he also explains the occurrence of Colles's fracture by "cross-breaking strain." This I proved as soon as I got the book in February, 1876, by making the fracture artificially in several dead bodies in the dissecting room of the Liverpool School of Medicine. Gordon's book contains the most exact account I know of Colles's fracture and of the mechanism of its cause.

I have never used the contrivance known as "Gordon's splint," though we had several specimens in the splint room of University College Hospital during my residence there in 1869 and 1870. Nor have I felt any disposition to use Carr's splint, which does not come up to my idea of what is wanted; in fact, no splinting can compare in efficacy with the "twisted splints" of sheet metal above referred to.—I am, etc.,

Liverpool, April 7th. RUSHTON PARKER.

SIR,—My old house-surgeon Mr. A. S. B. Bankart will, I feel sure, forgive me if I suggest that his criticism in your issue of March 16th (p. 491) of Messrs. Grasby and Trick's paper is somewhat lacking in generosity. Such reports by men, when dressers in fracture departments, can only be for good and may do something to dispel many popular illusions with regard to prognosis. The chief of the department is to be congratulated on having inspired and permitted the investigation. It must be admitted that the authors exposed themselves to criticism in that they drew broad deductions from a number of cases far too small to be of the slightest statistical value; yet, even if generalizations are admissible, I find myself absolutely unable to appreciate the argument put forward by Mr. Bankart.

As a member of the committee which drafted the British Medical Association's report of 1912 I am unlikely to minimize the importance of absolute restitution of alignment; it must, however, be admitted that in some cases of Colles's fracture in elderly and infirm women a bad result is preferable to the risk which a general anaesthetic would entail: further, it is not uncommon in my experience to fail to reduce the deformity completely by manipulation under a general anaesthetic, even with the aid of a wedge; in such cases comminution or constitutional defects not infrequently contraindicate open reduction. I must admit that I have never mastered the Jones technique. The method I teach and attempt to carry out myself is disimpaction by extension in dorsiflexion followed by adduction with palmar flexion.

After reading Messrs. Grasby and Trick's paper carefully a second time, I fail to see what grounds Mr. Bankart finds in it for his conclusion—that "at a great London teaching hospital a Colles's fracture is never properly reduced." Nor can I agree that "the usual results of the methods of treatment at present adopted" are invariably unsatisfactory. Surely Mr. Bankart cannot believe that his first statement can with truth be made of any hospital, and least of all with regard to the hospital where he received his early training and to which he is indebted for much of his success. His paper would endeavour to show that general surgeons know nothing of the treatment of Colles's fracture, and that orthopaedic surgeons know everything. I dislike these antitheses and antagonisms: we are all working in the same field for the advancement of knowledge, and such gibes contrast ill with a recent tribute to Arbuthnot Lane's contributions to orthopaedics by an orthopaedic surgeon.[1]

When reading Mr. Bankart's paper I felt that the application of extreme force which he advocates is dangerous, as I have seen the median nerve injured when apparently the force used was not unusual: but while preparing this note I find that this is dealt with by others in your issue of March 30th, so that further comment is unnecessary. Everyone knows how fallacious is a general impression of results, as was shown by the findings of the British Medical Association's Committee on Fractures referred to above. One cannot help thinking that if Mr. Bankart would look up his own cases after at least a two years' interval, he would find that his preconceived ideas did not entirely coincide with the results obtained. As a fact, it is up to Mr. Bankart to show a very high percentage of good results, for I gather that besides regarding Colles's as one of the easiest fractures to treat, Mr. Bankart is of opinion that it is always possible and in the patient's best interests to reduce the deformity. I rejoice to read that Mr. Bankart did at least carry away from Guy's one good principle—which is that, provided deformity is reduced, the particular type of splint or other retentive apparatus used is of relatively little importance; or conversely, if the displacement is not corrected,

[1] W. H. Trethowan, *Lancet*, January 5th, 1929, p. 50.

no apparatus can be expected to do this. It can only maintain the reduction when once obtained, and in a Colles's fracture the fragments once put into normal alignment impinge on one another so freely that very little more than firm support is needed.

I have read Messrs. Edwards and Clayton's paper with much pleasure and advantage, but cannot agree with Mr. W. A. Cochrane's comments on this in the *British Medical Journal* of March 9th (p. 477) as to the frequency of displacement of the lower end of the ulna. I find that my failures do not show this deformity, which hitherto I have not met with as a marked feature of this accident. I attribute most of my own bad results to secondary arthritis of the wrist or inferior radio-ulnar joint; this is caused by altered mechanics either due to defective restitution or to involvement of a joint surface by the fracture. But as I have not reviewed my results this must be taken as a mere impression, and therefore of little value.—I am, etc.,

London, April 6th. C. H. FAGGE.

SIR,—Those who, like myself, have for long considered the present methods of reducing Colles's fracture to be somewhat inadequate, should be grateful to Mr. Bankart for daring to blaze a new trail. His assumption that to disimpact a fracture impacted by force requires almost as great force to reduce it, is strictly logical, and no amount of argument to the contrary can affect it.

That some few specialists (and, of course, Sir Robert himself) have gained the knack of applying the requisite force by Jones's method is undoubted, but what of the general practitioner who is called upon to treat the majority of these cases? Needless to say, his results are usually no better than those published at the opening of this discussion—perhaps often very much worse. He does not see enough of these cases to enable him to acquire the knack of using Jones's method to its proper advantage. He needs a more direct method, and I think Mr. Bankart has pointed the way.

After all, Mr. Bankart's method is only another way of applying Sir Robert Jones's two forces, and to those who would hesitate to apply what may seem uncontrolled force over an orthopaedic wedge, in the manner of Mr. Bankart, the use of a modified Thomas's wrench may appeal.

By means of a Thomas's wrench the forces used by Sir Robert Jones are increased many times, and there is little danger of sudden strains on tendon or nerve.

It is the opinion of most surgeons, I think, that once the majority of these fractures are properly reduced they almost take care of themselves. The reduction is the vital point, and no amount of splinting in fancy positions, massage, or other accessories (the refuge of the inexpert fracture surgeon) will give a good result if the reduction is not anatomically correct.

It must not be forgotten, too, that in patients of advanced years the joints are quite ready to become the seat of osteo-arthritis, without the additional burden of an anatomical defect, however slight.—I am, etc.,

London, N.W., April 2nd. A. W. BAYLEY.

TREATMENT OF FRACTURES.

SIR,—Using the instances of Colles's and Pott's fractures, the treatment of bony injuries is being discussed in your columns in interesting fashion; old arguments are being reopened and new ones advanced.

The treatment of all fractures aims at re-establishment of bony continuity and restoration of function, while the methods and appliances employed are legion. Experience of many thousands of fracture cases at a base hospital in France convinced me of the truth reiterated by Mr. Ollerenshaw that the one essential to successful results is "continual supervision under one control." I would go further and say that the type of traction employed, the method of fixation, or the mobilization of the limb during fixation are utterly secondary to continuity of supervision. When in charge of a surgical division I had the duty of supervising some 450 beds for fractured femur cases; I refrained from formulating a routine technique of treatment, but with the help of the consulting surgeon managed to get my staff immobilized, and even obtained specialist status for them. Each had his own devices for treatment, but careful analysis of the results showed nothing to choose between the different groups of cases: for example, an average shortening of under 1 cm. was obtained in 500 cases treated in divers ways.

My chief object, however, in writing this letter is to draw attention to the work of Dr. Lorenz Böhler of the Umfalspital, Vienna, in the treatment of fractures. A period of post-graduate study there, recently, convinced me of the outstanding excellence of his results, and I feel that his methods should be better known here. The hospital is purely an accident hospital, specialized for this, and, I believe, financed by a group of insurance companies. The principle of treatment by Böhler is not new, being the fixation of the fracture in such a way as to allow of voluntary movement of the limb above and below the site of fracture; the methods employed, however, appear to me together to constitute a definite advance in treatment. They are: (1) The employment of local anaesthesia (2 per cent. novocain, 20 to 40 c.cm.) in the reduction of recent fractures, with almost dramatic effect, and the remarkable advantage that the patient can and does assist the manipulator in reduction. (2) Pin or ice tongs traction is used in conjunction with plaster and metal splints. (3) Internal fixation by operation is avoided, and, excepting only in fractures of the olecranon and patella, has not been used within the last three years. (4) Reduction is effected under extension and counter-extension of the limb—as, for example, in the germane instance of Colles's fracture—the flexed elbow was fixed by a band of webbing, while extension was applied temporarily to the palm and fingers by a mastisol bandage, the reduction of the impaction deformity being carried out by the surgeon in a supination-pronation manœuvre as described by Sir Robert Jones on March 30th (p. 619); a dorsal plaster splint extending to the knuckles allowed movement of the thumb and fingers and of the elbow.

Pott's and other ankle-joint fractures are similarly dealt with, fixation being effected by a plaster cast applied directly to the skin on the flexor aspect, carefully moulded to the joint, and carried to the heads of the metatarsals; to this are added circular bandages in which is incorporated a metal stirrup extending to 2 in. beyond the heel, and on which the patient is encouraged to walk on the third day. I have had the opportunity of using the method in two stout elderly women, with gratifying results: they were discharged from hospital at the end of a week, and both were fully able to perform household duties six weeks after the fracture. The greatest stress is laid on accuracy of reduction; "wet" films are taken through the moist plaster, and if apposition is unsatisfactory the process of reduction is repeated—the local anaesthesia lasts for about two hours. (5) Compound fractures are regarded as "urgents," and are operated upon, again under local anaesthesia, within two hours of admission; débridement, reduction, obliteration of dead spaces, and closure are effected, but no buried sutures (catgut) are used, the skin only being sutured; a window in the plaster allows of inspection and dressing. The results of these technical measures bear out what experience taught one in France—namely, that early excision and closure obviate suppuration; that immobilization at the site of fracture is the most important factor in overcoming suppuration when this is established; and that plates, screws, pins, and sutures are foreign bodies which tend to impair resistance and impede repair: their sole virtue is in their ability to effect immobilization of the fragments, and, since this can be achieved by other means, they should be discarded.

While in Vienna I was allowed to examine some sixty out-patients in Böhler's clinic, during the course of a routine inspection by the surgeon. Critical examination failed to reveal one result which could be regarded as indifferent by ordinary standards, while the number of amputations in case records was enviably small. I omit to mention that a massage or orthopaedic department does not exist at this hospital, the method used obviating the necessity for such a department.

Böhler's treatise on the treatment of fractures has been translated into English, or rather American, and is now in print; unfortunately, I have not yet got the name of

the publisher. In the meantime, those interested in the local anaesthesia technique will find a paper by Böhler on the methods of analgesia in the treatment of fractures in the March number of *Ars Medici*, published by the American Medical Association of Vienna.—I am, etc.,

Sunderland, March 29th. W. GRANT WAUGH.

THE INTRACUTANEOUS TUBERCULIN TEST.

SIR,—It is a pleasure to find, in Dr. Camac Wilkinson's further communication on the above subject, in your issue of March 30th (p. 621), that, while we may differ as to the use of certain words, our views on the more fundamental questions are not very far apart.

Like me, Dr. Wilkinson appears to hold the orthodox view that the tuberculin reaction is a specific allergic inflammatory condition. Why he should object to my using the expression "plaque of oedema" to describe the infiltrated part of the inflamed area I cannot imagine. Adami and McCrae, in their *Textbook of Pathology*, stated, under the heading of "inflammatory oedema," that "all acute inflammation is accompanied by a local increased passage of fluid out of the vessels," and my own sections of early allergic areas in tuberculous infection confirm this.

As to my selection of the third day as the best date for "reading" the reactions for comparative purposes, this date was chosen on the grounds of average measurements of reactions at different time-periods after the introduction of the tuberculin; and these measurements showed clearly that the third day was, on the whole, the best date for the purpose. Some authorities advocate a still earlier "reading." Dr. Ritter, for instance, in the *Handbuch der Tuberkulose* of Brauer, Schroeder, and Blumenfeld, expresses his views as follows: "Die Reaktion tritt nach 5–6 Stunden ein, erreicht nach 48 Stunden ihren Höhepunkt, um nach 2–3 Tagen wieder zu verschwinden." Dr. Wilkinson is quite right in saying that the induration "may persist for weeks." In my own case, it persisted for six weeks; but I do not contemplate undergoing a course of tuberculin treatment on that account.

I agree with Dr. Wilkinson, too, as to the interest attaching to *post-mortem* observations in this connexion. Burghardt found tuberculous lesions in 92 per cent. of cadavers of patients dying from "all causes" between the ages of 20 and 90 years; and Nägeli recorded a slightly higher percentage. These findings accord well with my 90 per cent. of "positives" to 1 in 1,000 tuberculin in healthy adult males.

In my opinion it is well to distinguish between the tuberculous infections which are consistent with health and those so extensive as to cause tuberculous disease. I admit that the borderline may be difficult to define, but I am not in favour of regarding the majority of our adult population as suffering from tuberculosis merely because about 90 per cent. are demonstrably infected with the tubercle bacillus.

Dr. Camac Wilkinson must forgive me if I forgo the pleasure of studying with him the histories of his cases. I can well believe that they are, as he says, "numberless," if he has accepted as his criterion of diagnosis a positive reaction to the intracutaneous tuberculin test.—I am, etc.,

Cardiff, April 5th. S. LYLE CUMMINS.

DENTAL CARIES AND VITAMIN D.

SIR,—I have read with great interest the correspondence arising out of the article by Mrs. Mellanby and Dr. Pattison on the association of dental caries with vitamin D deficiency published in the *British Medical Journal* of December 15th, 1928 (p. 1079), and venture to offer a few observations on the incidence of dental caries, the dietary, and the dental habits of two of the immigrant Asiatic races of British Malaya—the Chinese, and the Southern Indians or Tamils.

These races present a sharp contrast in their respective tendencies to dental decay. Among Tamils dental caries is rare, and the majority preserve a full set of excellent teeth into late middle age. Few have need of dental attention, and still fewer ever get any. On the other hand, the immigrant Chinese population suffers badly from caries of the teeth, and there are few towns, however small, where a Chinese dentist does not flourish. The following figures indicate the amount of dental caries in two comparable groups of adult coolies, Indian and Chinese, taken without selection from labour forces of the Kuala Pilah district of Negri Sembilan.

	Number Examined.	Number with Caries.	Number of Teeth Carious.
Chinese	100	43	163
Indians	100	6	7

These figures probably give a fair index of the prevalence of dental decay in the general coolie population.

The dietary of these races is essentially traditional, and does not depend appreciably on the local market produce. There is surprisingly little individual and diurnal variation. Both dietaries tend to be monotonous and unbalanced, but the Tamil diet is much poorer than that of the Chinese. In general it may be said that a Chinese coolie spends twice as much on food as a Tamil in similar employment. The diet of the former consists largely of polished rice, supplemented by a liberal daily consumption of vegetables fried in ground-nut oil. The Chinese are the vegetable gardeners of the peninsula, and are alive to the dietetic as well as the economic value of garden produce. Dried fish is a common addition, and pork, preferably fat, is added as often as means will permit—usually from once to four or five times weekly. Parboiled rice, which forms the basis of the Indian diet, is mixed with either dholl (husked and split pulses, chiefly the chick pea), maize, or dried fish, and flavoured with such curry stuffs as coriander, cardamoms, turmeric, and tamarind. Fresh vegetables, far from being the important item they form in the Chinese dietary, are included sparingly once every two to four days. Coconut oil is the only fat commonly used by coolies. Milk, butter, and eggs have no place in either Chinese or Tamil coolie diets.

The presence in the Chinese dietary of an abundance of green vegetables would appear to ensure a sufficiency of vitamins A and D. Most Chinese coolies work stripped to the waist for eight or more hours a day exposed to powerful solar irradiation in tin mines or on jungle clearings, so that deficiency of vitamin D is extremely unlikely. Moreover, the symptoms of vitamin D deficiency—rickets and osteomalacia—are rare in Chinese of the coolie class, while the relatively high degree of resistance to bacterial infection with the rarity of keratomalacia testifies to the general adequacy of vitamin A in their diet.

The Indian diet is a poor source of vitamins A and D, and although insolation is sufficient to prevent the appearance of symptoms of vitamin D deficiency, vitamin A starvation is far from uncommon. Keratomalacia is frequently seen, and in general the Tamil coolie puts up a poor fight against bacterial infection. This was well shown in the influenza pandemic of 1918, when the mortality of Indians employed on rubber estates of Negri Sembilan was 88.3 per thousand of estate Indian population, compared with a 20.4 mortality in estate Chinese.

Among these races, and in so far as vitamins A and D are concerned, there would thus seem to be no grounds for regarding dental caries as an avitaminosis. If vitamins have anything to do with the question it is possible that the anti-beri-beri vitamin B (which is shown by the distribution of beri-beri in these races to be commonly deficient in the Chinese diet, but never deficient in the Tamil diet) is also the caries-preventive factor.

A more likely explanation is the difference of dental habit and hygiene. Most Tamils clean their teeth in the early morning by chewing a small piece of charcoal into a fine pulp, which is rubbed with a finger over the surface of the teeth. The grinding of the charcoal by the molar teeth scours the biting surface, and cleans and polishes them by an efficient natural method. This is followed by a thorough mouth lavage, which is repeated after meals. Throughout the day the Tamil habitually chews the tough and fibrous areca nut, wrapped in a betel leaf, and mixed with a paste prepared from burnt cockle shells. This practice provides exercise for his teeth and jaws, and is

probably an important factor in the maintenance of his strong healthy teeth. Some Indians adopt the Sikh practice of biting a piece of the stem of a species of briar, and of scrubbing the teeth with the resulting brush-like end. Sikhs are accustomed to use the stem of the shrub Sinyonya (*Memecylon caeruleum*). This shrub has an acid juice which leaves a pleasant tingling sensation on the tongue and gums, and is reputed to have some value as an oral antiseptic and deodorant. Many other trees and shrubs have been adopted for this purpose, the most important being the marcosa and banyan trees.

So far as my observations go, Chinese coolies rarely clean their teeth, with the result that soft carbohydrate food collects in the pits and crevices, and initiates the development of dental caries. The comparatively few coolies who pay any attention to oral hygiene do so in a perfunctory fashion with a cheap toothbrush and water. The two factors which seemed to be most concerned in the maintenance of the Tamil's vigorous teeth—cleanliness and hard use—are both conspicuously absent.—I am, etc.,

J. W. FIELD,
Malayan Medical Service.

Kuala Pilah, March 2nd.

SIR,—In his letter of February 2nd (p. 225) Dr. J. Sim Wallace refers to the high incidence of dental caries among the children of Australia and New Zealand, where "sunshine is specially abundant, and the irradiation of ergosterol in the skin is amply provided for." The same objection has occurred to those of us in South Africa who have been thinking over the recent developments of the subject. Bright sunlight is available almost every day of the year to irradiate our skin and the food we eat. It is difficult to believe that there can be any deficiency of vitamin D, especially when we find that rickets is almost unheard of. In spite of this, however, dental caries is unfortunately only too common; in the opinion of some authorities the incidence is at least as great as, if not greater than, in England. Moreover, it is not confined to the European; although the fine teeth of the Bantu are proverbial, investigation has shown that dental caries is by no means uncommon, even among the native children, whose life in the kraal might almost be described as a perpetual sun bath.—I am, etc.,

PROTEIN THERAPY IN PUERPERAL INSANITY.

SIR,—The report by Dr. Vivian Barkin in the *British Medical Journal* of January 12th (p. 67) on the treatment of puerperal insanity by injections of T.A.B. vaccine confirms work which has been carried on in Victoria for the last five years. Dr. P. A. Lalor injected patients suffering from puerperal insanity with vaccines containing 100 million streptococci, 100 million *B. coli*, and 600 million staphylococci in each cubic centimetre. An initial dose of 0.5 c.cm. was given, and the dose increased by 0.3 c.cm. every four days till 1.5 c.cm. had been given in a dose. The injections were given subcutaneously. After an interval of a month, another series of double strength was given. The result has been extremely satisfactory in certain cases. The majority of patients with puerperal mania recover without difficulty by the usual methods of treatment, but a certain number remain in a stage of mental enfeeblement and do not seem to give any prospect of further improvement. Such patients should not be allowed to remain as chronic inmates of asylums without a trial of the vaccine therapy just outlined. In all, twenty cases have been treated; of these fifteen have improved sufficiently to leave the hospital and have since remained out with their friends. Some of them had been in the hospital upwards of three years, and had been considered chronic mentally enfeebled patients.

I regret that I am unable to give the exact statistics. The study was carried out by Dr. Lalor, who died in 1927, and was unable to complete his work, but I am personally satisfied that sufficiently good results have been obtained to show that all cases of post-puerperal mental enfeeblement should be given at least two courses of vaccine injections.—I am, etc.,

JOHN K. ADEY, M.B., B.S.Melb.,
Medical Superintendent, Sunbury Hospital for Insane.

Victoria, Australia, Feb. 24th.

LOCAL ANAESTHESIA IN OPERATIONS FOR HAEMORRHOIDS.

SIR,—Dr. P. Kennedy Murphy, in his letter of March 23rd (p. 574) on local anaesthesia in operations for haemorrhoids, speaks very favourably of this method and the uniformly good results obtained by him. He is not in favour of stretching the sphincter ani in the majority of cases, since he finds that it may cause pain, bruising, and damage to the sphincter. He is not in favour of a tube being inserted, as it is liable to cause severe pain.

As stated in my article, I invariably perform dilatation of the sphincter, but I have never met the disadvantages mentioned by him. I think they are all due, not to the method itself, but rather to the way it is performed, and that malhandling and the unnecessary force used are responsible for these complications. Very little force is required to paralyse the sphincter—especially with local anaesthesia; if loss of control follows, too much force was used at the time.

In conjunction with dilatation I use a tube wrapped round with a piece of gauze thickly smeared with antipyrine in vaseline, and orders are given to remove it as soon as the patient complains of any discomfort. Should it cause pain it is easily removed, but if retained it helps the passage of flatus and tends to prevent swelling and haemorrhage.

Dr. Murphy favours "ligature" for removing piles in most cases, which, as stated by him, is advocated by many proctologists in this country. As against "ligature," my contention is that (unless the piles are cut away) considerable masses of devitalized tissue are often left to slough off into the rectum—a far from aseptic receptacle; I hold that, in comparison with other techniques in use for the removal of pedunculated tumours situated elsewhere, this method seems somewhat unsurgical. (As a rule a cervical polypus is not left to slough off into the vagina after its pedicle has been ligatured.) When a pile has been cut off, with a ligature there is always a fear of it slipping.

As for suturing, my submission is that, all things being equal, where and whenever possible, a wound surgically closed is safer than if we rely solely upon the natural process of elimination and cicatrization.

Removal of large piles together with suturing is the best safeguard against sepsis and haemorrhage. There does not seem to be much difference, as regards drainage, between suture or ligature. Healing after suture is rapid; in normal cases the patients are up and about in a week. Infection of any kind is exceedingly rare.—I am, etc.,

T. HENRY TREVES BARBER.

London, S.W.7, March 23rd.

THE EARLY HISTORY OF PERCUSSION.

SIR,—John G. Crosse, or Cross (1790-1850), a Norwich surgeon who had received his training at St. George's Hospital under Brodie, wrote, in 1815, a brief work entitled *Sketches of the Medical Schools in Paris*, in which he gives an account of his experiences in the Parisian hospitals during the winter of 1814-15. He describes in an entertaining way various cases which came under his observation, such as Dupuytren's success in trepanation of the skull for a cerebral abscess (p. 102). Sir Norman Moore, in his life of Crosse in the *Dictionary of National Biography*, has referred to other interesting observations in Crosse's book, but no one appears to have directed attention to a most illuminating passage on percussion. It will be recalled that it was not until 1808 that Corvisart had resurrected Auenbrugger's thesis on percussion.

"I seldom entered the medical wards of the French hospitals," Crosse writes (p. 202), "without seeing the *percussion*

de la poitrine (as it was termed) put in practice, in order to learn the nature, situation, and extent of diseases of the chest. I could not ascertain, then or since, how far it deserves the confidence which French physicians place in it; but most of them hold it in high estimation as a diagnostic mark of the different diseases of the thoracic viscera."

In a footnote after "*poitrine*" Cresse explains rather naively, and with the tacit assumption that all his readers would be uninformed, just what is meant by percussion.

"The operation," he says, "is merely striking different parts of the thorax with the hand and judging from the sound that is produced, of the nature, situation and extent of the disease affecting the viscera within. It is unnecessary to say much about it here because so much concerning it may be found in some French books. Le Baron Corvisart has been at the trouble to translate a book on the subject (Auenbrugger's *Nouvelle méthode pour reconnaitre les maladies internes de la poitrine, par la percussion*, etc. . . .) which has greatly served to bring it into fashion."

That Cresse, who had just come from the medical schools of Dublin and London, should have been unfamiliar with percussion in 1814 suggests that the practice had not at that time found its way to the English clinics. It would be interesting to learn when, and by whom, it came to be first practised in England. Cresse's rather cautious commendation of percussion could scarcely have inspired confidence in its usefulness.—I am, etc.,

Magdalen College, Oxford, March 19th. J. F. FULTON.

UNIVERSITY OF LONDON PARLIAMENTARY REPRESENTATION.

SIR,—During the last five years Mr. McAdam Eccles has tried conclusions with me in three University contests, and has been soundly beaten in them all, the last occasion being his own candidature for a seat upon the Senate in 1927, when the University of London Graduates' Association, of which I am president, promoted the candidature of Mr. Walter Spencer, who won the seat, and by so doing, it is understood, eliminated the promising prospect of Mr. Eccles being nominated by the executive of the University of London Conservative and Unionist Association as the official Conservative candidate to oppose my re-election at the next election. Mr. Eccles's rancour at these successive defeats seems to have assumed the proportions of a personal vendetta against myself, which I do not intend to pursue in your columns, nor will you wish me to do so, but there are certain statements made in Mr. Eccles's letter upon which I would ask you to allow me to comment.

Mr. Eccles declares that the paragraph which you published in your issue of March 23rd is "inaccurate," but does not specify in what respect it is to be corrected. Perhaps you will therefore permit me to say that Sir Philip Magnus, late president; Dr. Sidney Phillips, late treasurer; Sir Edward Stern, late vice-president; Dr. G. T. Moody, late vice-president; Dr. Leonard West, late member of the executive, of the University of London Conservative and Unionist Association, are supporting my re-election to Parliament. The "inaccuracy" reproved by Mr. Eccles would seem to be confined to the description of these gentlemen as members of the executive, upon which they were included in February, 1929, but from which they were apparently removed subsequently to their signifying their support of myself—a removal which was not made public. For one not in Mr. Eccles's confidence it is obviously a little difficult to follow the kaleidoscopic changes in the personnel of his executive. But Mr. Eccles in turn is inaccurate in his statement made in your columns that his "fourteen" vice-presidents are united in opposing my re-election. The current list of officers of the University of London Conservative and Unionist Association still contains amongst its "fourteen vice-presidents" the names of Professor W. E. Dixon, F.R.S., and Dr. M. O. Forster, F.R.S., both of whom have authorized the inclusion of their names in my Executive Election Committee. As Mr. Eccles seems to control the executive of the University of London Conservative and Unionist Association, doubtless these names will also be removed in due course.

It is impossible to consider in detail all the five "cogent reasons" which Mr. Eccles gives for his executive's opposition to myself. I would select three only, which are, however, typical of his methods of controversy.

1. As a Conservative I gave my adhesion to the nomination of Sir John Rose Bradford as the official Conservative candidate at the by-election in 1924 *before* the announcement was made that the Labour Government at that time in office had appointed a departmental committee upon London University, which from its reference and personnel foreshadowed an attempt to impose upon the University the recommendations of the Haldane Commission. That announcement obviously altered the position entirely; I had consistently opposed, Sir John Rose Bradford had as consistently supported, the Haldane recommendations. I took the view that for the representation of the University, University considerations superseded party considerations. The University of London Graduates' Association took that view also, and subsequently nominated me (as they are doing now) as an Independent to contest the seat upon the University issue, which remained the principal issue throughout the election.

2. Mr. Eccles seriously asserts that his association is recommending the University electorate to unseat me in Parliament because I have "derided the scheme of Lord Dawson for the co-ordination of medical services on more than one occasion." Was there ever a more absurd "*non sequitur*"? This, his fourth, "cogent reason," is obviously an afterthought; my earliest reference, at no time derisory, to the "Dawson scheme" is made in a letter to the *British Medical Journal* of July 7th, 1928; but Mr. Eccles, in a recent letter to the *Times*, declares that his executive had resolved to oppose my re-election as early as February, 1926. The "Dawson scheme" for the co-ordination of medical services really means a scheme of co-ordination put forward, not by Lord Dawson, but by a consultative council under his chairmanship which reported in 1920, since which time it has remained a dead letter. At that date the voluntary hospitals appeared to be heading for bankruptcy; a special parliamentary grant of half a million sterling was required to save them from ruin. My views on the co-ordination of medical services differ from the recommendations of that council, principally in the role I would now assign to the voluntary hospitals, which have made such a marvellous recovery in the past nine years; at the date of the Dawson report it would probably have been imprudent to have suggested that the voluntary hospitals should be given the more commanding position which I think they ought to enjoy. But there is no antagonism between Lord Dawson and myself upon this subject; the contrary is the case, for we have acted in common in the defence of the voluntary hospitals both on the platform and in Parliament.

3. Mr. Eccles's fifth "cogent reason" is similarly anachronistic; his executive could not have been influenced, in 1926, by action taken by me in 1928. Moreover, that action is misrepresented by him; the motion seconded by me was to "refer the matter [of hospital services] back to the Council for further consideration." Why this harmless request should be a "cogent reason" for unseating me in Parliament surely calls for some explanation from Mr. Eccles.

Medical graduates of London University supported me strongly in 1924 for Parliament, and in 1925 for the Senatorial representation of graduates in medicine; since then I have put in five years' further work for the medical profession in the House of Commons, where I am the only doctor in active hospital and private practice, and able, therefore, to keep in touch with current medical opinion. The medical profession has too few representatives in Parliament to be likely to wish to unseat a sitting member of their own calling in favour of Mr. Eccles's nominee, whose lifework has been spent, not in the service of medicine, nor in the service of medical graduates, but in the service of the London County Council and of the Roman Catholic Education Council, and whose only connexion with the University is that he represents the London County Council on the present Senate—an office which he must vacate immediately, as London County Council representation upon the Senate ceases when the new statutes come into operation in May.

The attempt to make University representation a strictly party question, as Mr. Eccles is doing, is surely the best means of ultimately destroying University franchise altogether.

The action now taken by Mr. Eccles's executive conflicts with the expressed wish of the Central Conservative Office; in March, 1928, the chairman of the party, Mr. J. C. C. Davidson, wrote to the president of the University of London Conservative and Unionist Association protesting as strongly as he could against the nomination of another Conservative candidate to oppose my re-election. That Mr. Eccles's executive is now forcing the hand of the Central Conservative Office into adopting the executive's selection does not alter the general opinion, voiced by the Central Office, as to the unwisdom from a party point of view of thus wantonly splitting the Conservative vote. It was because of this action, in direct disregard of a plain expression of the wishes of the Central Office, that Sir Philip Magnus, Dr. Sidney Phillips, and other members of the executive, some of whom I have named above, have withdrawn from that body, and are warmly supporting my re-election. Mr. Eccles, in pursuance of a personal quarrel, has succeeded in hopelessly dividing the Conservative Association, a predominant section of which is to be found upon a preliminary list of my supporters containing nearly 3,000 names, which I shall shortly circulate to electors. It is perhaps not very hopeful for Mr. Eccles's appeal to medical graduates to support his nominee that more than one-fifth of the voters in this preliminary list are medical graduates.—I am, etc.,

London, W.1, April 8th. E. GRAHAM LITTLE.

MEDICAL TREATMENT AND THE APOTHECARIES ACT OF 1815.

SIR,—With reference to the recent proposed action by the Society of Apothecaries of London to recover a penalty against an unqualified practitioner, it may not be generally known that this society possesses an absolute legal right, by virtue of the Apothecaries Act, 1815, to prohibit the prescribing and dispensing of medicines by unqualified persons. The society still sues such persons from time to time. It has been judicially decided that a person acts and practises as an apothecary who professes to judge of internal disease by its symptoms and applies himself to cure that disease by medicine.

The Apothecaries Act, 1815, is a great landmark in the history of the medical profession. Prior to the passing of this Act medical education and training of practitioners were not compulsory by law, and consequently, although many held degrees or diplomas, a larger number possessed no such qualifications. After the Apothecaries Act became law no person was permitted to practise as an apothecary in England and Wales without the licence of the society, unless he had been in practice before the Act. At the same time, the privileges of the Universities and the Royal Colleges were preserved by the Act.

The Medical Act, 1858, under which all medical practitioners are now registered, does not prohibit unqualified practice *per se*. The preamble to this Act states that it was passed to enable persons requiring medical aid to distinguish qualified from unqualified persons. The Act merely prohibits the use of certain titles, such as physician, surgeon, doctor or bachelor of medicine, and also defines the term "legally qualified medical practitioner."

The Society of Apothecaries, in the first half of the nineteenth century, did much for the education of the general practitioner by instituting examinations and courses of training. About the year 1850 a preliminary examination in arts was imposed on all the society's licentiates, some ten years before the General Medical Council made such a requirement obligatory on all medical students.

It is interesting to note that the *Medical Register* of 1873 contained the names of some thirty survivors whose legal right to registration rested on the basis of being in practice prior to August 1st, 1815, the date on which the Apothecaries Act became law.—I am, etc.,

R. B. F. FRAZER, L.R.C.P. and S.Ed.,
London, N.W., March 23rd. Barrister-at-law.

ERRORS IN DOSAGE.

SIR,—The recent case, as reported in the daily press, where fatal poisoning occurred through an overdose of thallium acetate occasioned by a misreading of the position of the decimal point would seem to imply that the metric system in prescription writing afforded greater chances of error than the apothecary's system. This recent case, however, had a complete parallel some months ago, where death from an anaesthetic occurred through the drachm symbol (ʒ) being mistaken for the ounce (℥). Neither system can therefore be considered fool-proof, the minimal error in the first being tenfold and in the second eightfold. Both instances, however, provide a strong argument for the more extensive use of tablet or ampoule medication where a new, relatively unfamiliar, or potent drug is concerned. It is obvious that here the possibilities of error on the dispenser's part are reduced to a minimum, the variation in dosage between the various tablets of a given substance as issued by the majority of drug houses being small, and a patient who was instructed to take ten tablets, say (instead of one) three times a day would certainly raise a query.

It would be a thankless task to attempt to wean the average patient from "the bottle" as far as familiar complaints and their equally familiar remedies are concerned, but now that so many valuable new preparations are being placed on the market in tablet form, which is both safe, convenient, and cheap, physicians would do themselves a valuable service in broadcasting the idea that "every tablet is not necessarily aspirin." I enclose my card, and am, etc.,

London, S.W.5, April 8th. G. H. M.

*** The note in our medico-legal column this week (p. 712) indicates that the error in the thallium acetate case arose not from misreading a decimal point on the prescription, but from the misplacement of a decimal point in the course of converting from one system of measurement to another.

Obituary.

R. L. MACKENZIE WALLIS, M.A., M.D.,

Lecturer in Chemical Pathology, University of London; late Chemical Pathologist, St. Bartholomew's Hospital.

DR. ROBERT LAUDER MACKENZIE WALLIS, who died on April 1st after a short illness, at the early age of 43, was at school in Cambridge, and afterwards graduated B.A. from Downing College, taking a first class in the Natural Sciences Tripos. He studied advanced physiology for Part II of the Tripos, and after leaving Cambridge he was appointed lecturer in chemical physiology at University College, Cardiff. In the autumn of 1911 he came to London to work in the laboratory of chemical pathology at St. Bartholomew's Hospital, and was appointed demonstrator in chemical pathology in 1912. He succeeded Sir Archibald Garrod as lecturer in chemical pathology in 1919, and was later appointed chemical pathologist to the hospital.

Mackenzie Wallis had a real interest in clinical work, an interest which was illustrated on an occasion when a physician asked his assistance as a chemical pathologist in the investigation of a patient in hospital suffering from glycosuria. Wallis was unqualified at the time, and was not known to have any knowledge of clinical medicine, but he recognized the condition as one of bronzed diabetes by the facies, and was the first to make the correct diagnosis in a patient who had already passed through several hands. From the comparative isolation of his laboratory, although fully occupied with routine work and original research, he pursued his clinical studies with such assiduity that he obtained the diploma of L.M.S.S.A. in 1913, and in 1919 he graduated M.D.Camb., and was awarded the Horton-Smith Prize for his thesis.

In the war he held a commission as temporary captain R.A.M.C., and was sent on service to India, where he served on the staff of the 34th General Welsh Hospital at Deolali. His great ability was recognized by the Government of India, and he was afterwards seconded for special

service in the Parel Laboratory, Bombay. Although pressed by the Government at the close of the war to continue his work in Bombay he chose to return to St. Bartholomew's Hospital, where he once again became absorbed in his work.

He was a man of tireless energy and great originality of thought. An example of the imagination that he infused into his research is shown by his idea of sulphaemoglobinaemia as due to bacillary action, an idea which led to his discovery of the nitrosobacillus in the saliva and faeces of persons suffering from this disease. His mastery of technical detail is illustrated by his modification of Folin and Wu's method of blood sugar estimation, as a result of which the analysis can now be made with drops of blood obtained by finger-prick in place of veni-puncture. He was the first to show by blood sugar curves that the glycosuria of pregnancy is due to overaction of the pituitary gland, and he was the first to demonstrate an increase of diastase in the urine in some forms of kidney disease occurring in pregnancy. The variety of his interest and the wideness of his knowledge is evident in his papers on metabolism in the insane, on protein hypersensitivity in the diagnosis and treatment of a special group of epilepties, and numerous contributions on gastro-intestinal disease. By his co-workers he will be best remembered for his interest in diseases of the pancreas and his critical appreciation of the value of chemico-pathological methods in their diagnosis.

His friends will always remember the self-sacrificing help in their work and difficulties that he was ever ready to give them; his industry and courage—a courage which never left him even in a grave illness from which he recovered—was an example to them, as was his enthusiasm an inspiration. He leaves a widow and three children.

Dr. LUCY ELEANOR SMITH, who died on March 23rd, was one of the first two women graduates of Queen's College, Cork, obtaining the degrees M.B., B.Ch., B.A.O. in 1898; she proceeded M.D. in 1902 and received the D.P.H. of the Royal Colleges of Physicians and Surgeons of Ireland. Among the appointments she had held were those of physician for thirty years to the City and County Lying-in Hospital, Cork; examiner for the Central Board of Midwifery in Ireland; and visiting physician to the Home for Protestant Incurables, Cork. She was also visiting physician to the prison for women in Cork up to the time of the establishment of the Irish Free State. Dr. Smith took an active interest in the progress of the British Medical Association, of which she had been a member for thirty years; she was president of the Munster Branch in 1909, a representative in 1910, a member of the Branch Council from 1911 to 1928, and an accredited correspondent of the *British Medical Journal*. She was the pioneer woman doctor in Cork, and in spite of considerable opposition won her way to an outstanding position, associating herself particularly with maternity and child welfare work. Her death is mourned by many colleagues and friends, attracted no less by her personal character than by her distinguished achievements and valued services.

Dr. REGINALD INGLIS DOUGLAS who died recently was born in 1879, and received his medical education at the University of Durham and St. Bartholomew's Hospital. He obtained the diplomas M.R.C.S., L.R.C.P. in 1904; in 1906 he graduated M.B., B.S.Durham, and two years later he became D.P.H. He held house appointments at St. Bartholomew's Hospital, St. Luke's Hospital, and the Metropolitan Hospital, and in 1908 commenced practice in Rome among the British colony. In the following year he organized the British relief expedition to assist the victims of the Messina earthquake, and was awarded the Order of the Crown of Italy. At the outbreak of war he joined the British Red Cross in France, and subsequently received a commission in the R.A.M.C. In 1916 he went to Gallipoli, where he stayed until the evacuation, after which he served in Italy. With the termination of the war he was appointed medical officer to the Ministry of Pensions at Newcastle-on-Tyne, and in 1922 he began to practise in Bedford, becoming also medical officer to the prison there. Dr. Douglas was a member of the British Medical Association. He leaves a widow, two sons, and a daughter.

Dr. JOHN CLARKE FENWICK, who died at his home in Winnipeg, Manitoba, on March 2nd, at the age of 68, was a native of Durham. He received his medical education at the University of Durham and at the Royal College of Surgeons of Edinburgh, where in 1887 he was awarded the Jenner medal for surgical operations. In 1891 he obtained the diplomas L.R.C.P., L.R.C.S.Ed. and L.R.F.P.S.Glas. In 1911, after practising for some years in Sunderland, Dr. Fenwick went to Canada, where he established himself in Winnipeg, and became one of the directors of the Victoria Hospital, and carried on the largest workmen's compensation practice in the province. He is survived by one son. Mr. Alexander Gibson, F.R.C.S., writes from Winnipeg: "The passing of John Clarke Fenwick has left a gap which will be hard to fill. He was one of those whose virtues do not lie on the surface. The thought of his personal advantage never weighed for a moment against his scrupulous adherence to what he considered to be right. His somewhat brusque and direct manner made him not always popular, but precisely for such qualities as these, combined with his fearless determination to pursue what he considered the right path, was he respected and admired by those with whom he came most closely in contact. To the end of his life he continued to read and to study, and within a few days of his death he discussed with the writer medical subjects of a controversial character, in which he showed a knowledge of the latest work."

Dr. FRANK RANDOLPH SEAGER, who died on March 5th, completed his medical education at Edinburgh and Glasgow in 1899, obtaining the diplomas L.R.C.P. and L.R.C.S.Ed., and L.R.F.P.S.Glas. After holding the appointments of house-physician at the Edinburgh Royal Infirmary and house-surgeon at the Burton-on-Trent Infirmary he went out to Turkish Arabia, where he was honorary physician to H.B.M. consulate at Basrah. In 1911 he settled in Warrington, and for sixteen years was engaged in an ever-growing practice, combining a talent for accurate diagnosis with a remarkable power of reading character, and unflinching devotion to duty. In 1927 health conditions necessitated his removing to a more congenial climate, and he took over a country practice at Wolston near Coventry, where he improved until the recent epidemic of influenza overtaxed his strength and led to his death. He leaves a wife, a son, and a daughter.

Dr. THOMAS CARLYLE BEATTY, who died at Clacton-on-Sea on March 25th, was born at Seaham, Durham, in 1850. He received his medical education at the Universities of Aberdeen, Edinburgh, and Durham, taking the diplomas L.R.C.P., L.R.C.S.Ed. in 1873 and the L.S.A. in 1874; in 1879 he obtained the F.R.C.S.Ed., and in 1895 the M.D. of St. Andrews. After many years' professional work on the Italian Riviera, where he was physician to the Stabilimento Idropatico ed ellettrico Sella, he returned to England and built up a large practice at Clacton-on-Sea. When war broke out Dr. Beatty, though in his sixty-fifth year, was appointed honorary anaesthetist to the Middlesex Hospital, Clacton, and throughout the war he carried out the duties of this post with devotion and often at great risk to himself. By his sympathy and unselfish personality he won the deep esteem of all his patients, and he will be greatly missed in the district where he practised for so many years. He is survived by a widow and three daughters.

Dr. RICHARD HEDDEN, who died on March 28th, at his residence in Bideford, at the age of 68, received his medical education at Guy's Hospital; he obtained the diploma L.S.A. in 1905, and the M.R.C.S., L.R.C.P. in 1896. From 1899 to 1919 he practised in Honiton, after which he retired to Bideford, where he gave active support to the local hospital, serving as a member of its committee, and holding the post of honorary treasurer since 1924; he was also honorary secretary of the Bideford Nursing

Association and honorary secretary and treasurer for the maternity work. Dr. Hedden was a member of the British Medical Association and was a member of the Executive Committee of the Barnstaple Division from 1923 to 1928; he was also a member of the Devonshire Association. He was married twice and his second wife survives him.

Dr. JAMES MCHUGH, who died on March 31st after a few days' illness, received his medical education at Liverpool, where he was awarded the Derby Exhibition in Medicine. He graduated M.B., Ch.B. in 1927 with first-class honours and distinctions in medicine and surgery; in the same year he obtained the diplomas M.R.C.S., L.R.C.P. He spent twelve months as a resident at the Liverpool Royal Infirmary, first as a house-surgeon and then house-physician, after which he became assistant to Dr. Rowlands of Waterloo six months ago. A colleague writes: McHugh's death brought to a close prematurely a career which promised to be of brilliant and faithful service to the community and his profession. By a wide circle of friends he will be missed as a loyal colleague, a charming personality, and a faithful friend.

The following well-known foreign medical men have recently died: Professor OTTO HERMES, formerly director of the surgical department of the Rudolf Virchow Hospital, Berlin; Professor EDUARD MÜLLER, director of the medical polyclinic at Marburg, aged 52; Dr. WILHELM WIECHOWSKI, professor of pharmacology at Prague; Dr. PIERRE KOVINDJY, a Paris physiotherapist; Professor LASSER, formerly head of the medical department of the Würtemberg War Office and author of numerous works on epidemiology and neurology, aged 69; Dr. ALBERT FREIHERR VON SCHRENCK-NOTZING, a writer on hypnotism, aged 67; Dr. HUGO SALUS, a gynaecologist and lyric poet of Prague; and Dr. J. W. H. JOHNSSON of Copenhagen, author of several studies on the history of medicine, aged 60.

Medico-Legal.

POISONING BY THALLIUM ACETATE.

ON April 8th a London coroner's jury returned a verdict of death from poison accidentally administered in the case of three brothers, aged respectively 10, 7, and 5 years, who had been treated for ringworm of the scalp by the internal administration of thallium acetate at a hospital.

The value of this drug in the treatment of tinea capitis, based on its property of producing a total, though temporary, alopecia, was first recognized early in the present century by Sabouraud, but it was not until 1918, when Professor R. E. Cicero discovered that by carefully assessing its dosage in terms of body weight he was able to prevent the severe toxic symptoms occasionally attending its administration, that the employment of thallium acetate became at all general. The dose recommended by Cicero, of 8 milligrams per kilogram of body weight with a maximal dose for any patient, however heavy, of 0.3 gram, has been found by dermatologists generally to produce satisfactory results, and it is clear from the evidence at the inquest that the doses actually ordered for the three boys fell well within these limits. On chemical analysis, however, it was found that each dose of the solution administered contained 5.6 times as much thallium acetate as was ordered in the prescription, a blunder which arose not from any carelessness in the actual dispensing, but from the fact that the hospital pharmacist had made a mathematical error in converting the amounts of the prescription from the metric to the apothecaries' measure.

In a rider to its verdict the jury expressed the view that there should be a better system at the hospital for the checking of weights and measures. But such a system can be applied effectively only in an institution, and the position of the pharmacist in private practice, who must frequently make calculations in converting from one numerical symbolism to another, is in no way affected. The coroner stated in his summing-up that thallium acetate being a Continental drug its dosage had been worked out on the decimal system. But the need would appear to be for the adoption in the case of all prescriptions of a uniform system of pharmaceutical measurement and symbols. At present, error may arise not only as a result of arithmetical miscalculation, but from the existence of symbols similar in appearance but very different in meaning. The symbol gr., for example, in apothecaries' measure, representing the grain, is commonly used in prescriptions written on the metric system to represent gram. It is, however, only in Britain and in the British Empire that such confusion is likely to arise, and this tragic case provides a further reason for the supersession of the apothecaries' system of measurement by the decimal system adopted practically universally on the Continent and in America.

Universities and Colleges.

UNIVERSITY OF LONDON.

THE annual service at Westminster Abbey will be held on Presentation Day, May 8th, at 5.30 p.m.

A course of six lectures on dietetics will be given by Professor S. J. Cowell at St. Thomas's Hospital on May 2nd, 9th, 16th, 23rd, 30th, and June 6th at 5 p.m.

Professor A. J. Hall (Sheffield) will give two lectures at University College on some of the sequels of epidemic encephalitis (lethargica), with lantern and cinematograph illustrations, on May 3rd and 10th at 4 p.m.

Three lectures on drug-like actions of some food constituents will be given by Professor E. Mellanby at University College on April 29th, 30th, and May 1st at 5.15 p.m.

A course of two lectures will be given by Dr. J. J. R. Macleod, F.R.S., Regius Professor of Physiology in the University of Aberdeen, on the physiology of glycogen, at the London Hospital Medical College on May 16th and 17th at 5.30 p.m.

Two lectures on the psychology of dementia will be given at University College on May 29th and 30th, at 5.30 p.m., by Dr. E. D. Wiersma, Professor of Psychiatry and Neurology in the University of Groningen.

Dr. A. Brachet, Prosecteur and Professor of Anatomy in the University of Brussels, will give three lectures on experimental embryology at University College on May 28th, 29th, and 31st at 5.30 p.m.

UNIVERSITY OF BIRMINGHAM.

Post-Graduate Demonstrations.

A COURSE of post-graduate demonstrations will be given at the General Hospital, Birmingham, on Tuesdays, and at the Queen's Hospital, Birmingham, on Fridays, from 3.30 to 5 p.m., from April to July, commencing on April 23rd at the General Hospital and on April 26th at the Queen's Hospital. The course will be given by members of the medical and surgical staffs, and will include demonstrations on medical, surgical, and gynaecological cases, nervous diseases, ophthalmic cases, diseases of ear, nose and throat, radiology, venereal diseases, children's diseases, etc. Particulars may be obtained from the clerk to the Clinical Board, the University, Edmund Street, Birmingham.

Lectures.

The William Withering Memorial Lectures, open to all members of the medical profession, will be delivered in the large theatre of the medical school at 4.30 p.m. on Wednesdays, April 24th, May 1st and 8th, and June 19th and 26th, by Dr. Charles Singer, who has chosen for his subject "Epochs of medical history."

Dr. Matthew B. Ray will deliver a lecture on the spa treatment of chronic non-tuberculous arthritis at 4 o'clock on Thursday, May 16th, in the Medical Lecture Theatre (Edmund Street Buildings).

The Ingleby Lectures will be delivered on May 23rd and 30th at 4 o'clock in the Medical Lecture Theatre by Dr. H. Charles Cameron, whose subject will be "Some types of septic infection in the newly born."

ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

AT the monthly business meeting of the College, held on April 5th, the following candidates, nominated on January 4th, for the Fellowship were unanimously elected by ballot: Nicholas M. Cummins, Robert C. Cummins, and Robert E. Steen.

The following, having passed the Final Conjoint Examination, were admitted to the Licences in Medicine and Midwifery: A. P. Dolan, Mary A. Kealy, A. Mejias.

A letter was read from the Registrar of the University of Capetown inviting the College to nominate delegates to the celebration of the centenary of the South African College in October. The nomination was left in the hands of the President.

The Services.

AUXILIARY R.A.M.C. FUNDS.

THE annual meeting of the members of the Auxiliary R.A.M.C. Funds will be held at 11, Chandos Street, W.1, at 2.30 p.m., on Friday, April 26th, when the annual report and financial statement for the year ended December 31st, 1928, will be presented and the officers and committee for the current year elected.

Medical News.

IN celebration of the completion of its new building in Broad Street, Holborn, the Royal Westminster Ophthalmic Hospital will hold a Festival Dinner at the May Fair Hotel on Thursday, May 2nd, with Lord Ashfield in the chair.

AT a meeting of the Eugenics Society on Wednesday, April 24th, at the rooms of the Royal Society, Burlington House, Piccadilly, Mr. C. J. Bond, F.R.C.S., will lecture on hemilateral asymmetry in animals and man, and its relation to cross-breeding. The chair will be taken at 5.15 p.m. by the president, Sir Bernard Mallet. Visitors are welcome.

A NEW series of public debates will be held at the London School of Economics this year, in aid of King Edward's Hospital Fund for London. Particulars can be obtained from the Secretary of the Fund, 7, Walbrook, E.C.4.

AT a meeting of the Royal Society of Arts on Wednesday, April 17th, at 8 p.m., at the Society's House in John Street, Adelphi, Mr. F. E. Lamplough, M.A., will read a paper on the properties and applications of vitaglass, illustrated by demonstrations. Professor Leonard Hill, F.R.S., will take the chair.

THE Fellowship of Medicine announces that there will be a series of eight lecture-demonstrations at the London School of Hygiene and Tropical Medicine on Tuesday and Thursday afternoons at 2 p.m. from April 9th until May 2nd. A two weeks' course for the general practitioner will be held daily from April 15th to 25th at the London Temperance Hospital from 4.30 to 5.30 p.m. On successive Wednesdays, at 5.15 p.m., from April 10th to May 1st, a series of lecture-demonstrations on light and heat therapy will be given at the Royal Free Hospital; at the Royal Waterloo Hospital there will be a course in medicine, surgery, and gynaecology from April 15th to May 3rd, occupying the greater portion of each day. From April 15th to May 10th the West End Hospital for Nervous Diseases will give a series of daily lecture-demonstrations, illustrated by cases, at 5 p.m.; minimum entry, ten. The Fellowship of Medicine proposes to hold its first evening course for the M.R.C.P. diploma from May 7th to June 28th. Lectures will be given on Tuesdays and Fridays at 8.30 at the Medical Society of London by well-known authorities on diseases of the brain, nervous system, heart, blood, alimentary system, spleen, and biochemical methods. Fees, 10s. 6d. per lecture or £5 5s. for the complete course of sixteen lectures. Application should be made to the secretary of the Fellowship, 1, Wimpole Street, W.1, for further information about this course; detailed syllabuses of the various other special courses can also be obtained, and information about the general courses available at hospitals affiliated to the Fellowship.

THE Baylis-Starling Memorial Scholarship, founded in commemoration of Professor Sir William Maddock Bayliss and Professor Ernest Henry Starling, has an annual value of about £120, with exemption from tuition fees, and is tenable at University College, London. The scholar will be required to follow a course of study approved by the Jodrell Professor of Physiology involving a training in the principles of, and methods of research in, physiology and biochemistry. Candidates must send their applications to the secretary of University College not later than May 15th.

THE High Commissioner for the Union of South Africa has received from his Government an intimation that, pending the establishment of reciprocity with the United Kingdom, persons holding British degrees or qualifications in dentistry or pharmacy who were not born or domiciled in South Africa are not eligible for registration or entitled to practise in the Union.

A POST-GRADUATE course on the radiological diagnosis of various pulmonary diseases including tuberculosis will be held at Strasbourg from June 24th to 30th. In addition to lectures and demonstrations various sanatoriums will be visited. The course is limited to fifteen persons, and early application should therefore be made to Dr. E. Vaucher, 8, Quai Finkwiller, Strasbourg. The fee is 300 fr., and a certificate will be obtainable at the conclusion of the course.

A POST-GRADUATE course in French in venereology and dermatology will be held at Strasbourg, from October 7th to November 16th, under the directorship of Professor L. M. Pautrier. The course will include lectures, clinical instruction, and pathological demonstrations; various therapeutical procedures will be illustrated. During the same period a series of twenty lectures will be given on the principal laboratory methods and the general pathological anatomy of dermatoses, with individual tuition. The fee for each course is 300 fr. Further information may be obtained from Dr. Roederer, Dermatological Clinic, Civil Hospital, Strasbourg.

THE Association of French-speaking Gynaecologists and Obstetricians will hold its ninth congress at Brussels from October 3rd to 5th, when papers will be read on the relations between the hypophysis and the female sexual organs, myomectomy during and apart from pregnancy, and indications for and technique of sterilization in women.

AT the congress of French-speaking dermatologists and syphiligraphists to be held at the Hôpital St. Louis, Paris, next July a medal and bust will be presented to the president, Dr. Sabouraud, who is retiring from the hospital staff at the end of the year. Subscribers of 100 francs and over, which should be sent to the treasurer, Dr. Maurice Pignot, 2, Rue de Grébauval, Paris, will receive a bronze replica of the medal.

THE twentieth French Congress of Medicine will be held at Montpellier on October 15th under the presidency of Professor Vedel, when the following subjects will be discussed: etiology, pathogenesis, and physiopathology of scarlet fever, introduced by Cantacuzène of Bucarest, P. Teissier, Coste, Sacquepée, and Liégois of Paris; arterial hypotension, introduced by Lian and Blondel of Paris; treatment of anaemia, introduced by E. Hedon and Jeanbrau of Montpellier, Lambin of Louvain, and J. Carles of Bordeaux. Further information can be obtained from the general secretary, Professor Rimbaud, Rue Levat 1, Montpellier.

THE sixteenth Congress of the German Dermatological Society will be held from August 5th to the 7th at Königsberg, when the following subjects will be discussed: investigation of [illegible] introduced by Professor Köhler of [illegible] Siemens of Munich; prognosis and treatment of congenital syphilis, introduced by Professor Hoffmann of Bonn; and determination of the cure of gonorrhoea, introduced by Professor Jadassohn of Breslau. Further information can be obtained from Professor W. Scholtz, Univ. Hautklinik, Königsberg.

A COMMITTEE composed of Professors Borst, Doederlein, Romberg, and Sauerbruch has awarded the Sofia A. Vordhoff-Jung prize for the best work on the etiology of cancer to Professor Katsusaburo Yamagiwa of Tokio University.

DR. WILLIAM B. H. MASSIAH has been appointed a member of the Legislative Council of the Island of Barbados.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9961, 9962, 9963,* and *9964* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*, telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

INCOME TAX.

Cash Basis and Book Debts.

"MEDICUS" has completed his first year in a new practice, and has been informed by the inspector of taxes that his declaration of profits must be based on the book debts rather than on cash receipts—that is, that he must add to the amount of his cash receipts in his first year the amount of debts due but unpaid at the end of that year.

*** Income tax is payable on the amount of the profits earned, whether they have been gathered in as cash or are still outstanding. The inspector's attitude is therefore correct, with one rather important qualification. The addition to the cash

debts should be that amount of the outstanding debts which will probably be recovered. "Medicus" should therefore scrutinize carefully the list of debts and deduct from the total any sums which he considers he will have to forgo on specific items.

LETTERS, NOTES, ETC.

TREATMENT OF HAEMOPTYSIS: CORRECTION.

WE regret that, through misreading of the manuscript, a somewhat serious error appeared in Professor Ascoli's note on the treatment of haemoptysis published at page 549 of the *Journal* of March 23rd. The concentration of adrenaline which must be used (see line 9) is a 1 per *thousand* solution, not, as printed, 1 per cent. This is *followed* by 2 c.cm. of water to wash the adrenaline along the bronchial surfaces.

TREATMENT OF INFLUENZA.

DR. H. J. CLUTTERBUCK (Llanelly) writes: In answer to Dr. Tressie Pires's inquiry about the effectual dose of the compound powders of aspirin 5 grains, phenacetin 2½ grains, pulv. doveri c excipient 2½ grains for children in influenza and many other febrile conditions (March 30th, p. 628), I think I was one of the first to use this compound, and I received very valuable advice from Sir Archdall Reid of Southsea. I give the powder as follows. For children between the ages of 2 and 5 I break one tablet, consisting of the above doses, into four parts, and administer one part every two hours, the last one always being given in spite of any marked improvement in the condition, which is almost without exception. In children from 5 to 12 years I break the tablet into three parts and give one every two hours. For those over the age of 12 the dose is the same as for the adult. Sir Archdall Reid, in a letter to me dated June 10th, 1921, wrote: "I have not given such big doses as you have, but I dare say you are right." He advised me to try them in measles and mumps. I did so and got, as he said, amazing results. I have seen very few cases of measles in the last ten years; those that I did see cleared up in a few days. I saw a patient last week with a temperature of 104.6° and pulse 130. I gave him two tablets at once, and one every two hours until he had had five altogether. Twenty-four hours afterwards the temperature was 100.4°; thirty-six hours afterwards it was normal. The most interesting thing to me is that many of these cases develop a form of pustular herpes labialis, showing that the pneumococcus is not far away. Sir James Kingston Fowler used to say that herpes labialis was a pneumococcal infection, and in my opinion these tablets have saved many patients from pneumonia.

DR. A. DINGWALL KENNEDY (Wick) writes: I have read with great interest the letters by Dr. Garry Simpson (March 2nd, p. 430), Dr. W. Bastian (March 9th, p. 486), and Dr. Tressie Pires (March 30th, p. 628), relating the beneficial results which almost invariably followed the giving of aspirin, phenacetin, and pulv. ipecac. co. Without doubt this powder may well be regarded as a specific if given early in a case of typical influenza. It has only one drawback: the pulv. ipecac. co. is not always well borne, and not a few patients feel sick after it. For over twenty years I have employed the following powder, with equally good result, in all those cases of influenza which came early (within the first few days) under my care: aspirin 10 grains, phenacetin 2 grains. Twelve powders are sent, one to be taken every four hours. If given the first day the temperature usually fell to normal within twenty-four hours. In spite of the lack of the opiate, the pains in the head, back, and limbs were relieved by the first powder. Two grains seems a small dose for phenacetin, but it is sufficient to accentuate, if not actually render effective, the action of the aspirin. In all cases of sore throat of the rheumatic type it is equally effective, and even in cases of rheumatic fever, where tolerance to the salicylates is becoming exhausted, I have found this powder act well. In these cases, however, the addition of Dover's powder is often required. In all my experience of prescribing many thousands of these powders I have not yet come across a single case in which the heart would appear to suffer in the slightest degree from the aspirin. My cases include many patients whose hearts have already suffered the worst that rheumatic fever can inflict in the way of valvular defects. In children I give doses according to age, but for infants of 2 or 3 years I prefer sodium salicylate with sodium bicarbonate; of each 3 to 5 grains.

TREATMENT OF EMPYEMA.

DR. J. R. KEITH (Southsea) writes: With regard to the treatment of empyema I should like to mention a method of treatment which is not so well known as it should be. In the book *Clinical Memoranda for General Practitioners*, by Dr. A. T. Braud and myself, it is stated that in the treatment of post-empyema sinus Klapp's suction glass will be found to be of yeoman service. We recorded the case of a woman who had been operated upon for empyema, following an attack of acute croupous pneumonia. A profuse discharge, accompanied by a high evening temperature, continued for several weeks, in spite of treatment, which included the use of bismuth paste. On the application, however, of a Klapp's suction glass twice daily for five minutes at a time, the situation changed dramatically, the wound being completely healed and the temperature reduced to normal in three weeks. This glass or glasses generally seem to be called in this country "Bier's cups," but from information supplied to us in 1907 by F. A. Eschbaum, manufacturer of surgical instruments at Bonn-on-the-Rhine, we were led to believe that the chief merit of inventing them belonged to R. Klapp, assistant to Auguste Bier, professor of surgery at Bonn before his removal to Berlin, and who was afterwards head of the surgical clinic in urology at Griefswald University.

EOSINOPHILIA IN INSULIN THERAPY.

DR. R. CHALMERS (Darlington) writes: As a corollary to the interesting observation of Drs. Lawrence and Buckley of the occurrence of eosinophilia in insulin therapy (March 30th, p. 597), one would expect evidence from time to time of this spasmophilia tendency to occur in such cases. This has been shown to occur by one observer, who found that the convulsions which appear in the hypoglycaemic reactions following on overdosage with insulin are of the nature of tetany, and can be removed by calcium chloride and parathyroid extract, although this does not affect the low blood sugar.

LONGEVITY.

DR. H. F. BASSANO (Ventnor, I.W.) writes: I should be interested to hear if any of your readers can beat the following records taken from my death certificate book. The entries are consecutive, and date from October 26th, 1927, to April 6th, 1929. The deaths are registered in the Ventnor district only. You will observe that of eighteen deaths the average age is over 80. I venture to think this must be almost unique.

Sex.	Cause of Death.	Age.	Sex.	Cause of Death.	Age.
F	Cardiac	91	F	Carcinoma	83
F	Carcinoma	94	F	Cardiac	78
F	Cerebral haemorrhage	76	F	Cardiac	82
F	Chronic nephritis	72	F	Carcinoma	93
M	Cardiac	58	F	Carcinoma	85
F	Cardiac	81	F	Influenzal bronchitis	76
M	Cardiac	81	F	Cardiac	83
F	Cardiac	76	M	Influenzal bronchitis	83
F	Cerebral thrombosis	77	F	Cardiac	72

UNUSUAL SYMPTOMS OF PROSTATE ENLARGEMENT.

DR. E. B. FFENNELL (Walton-by-Clevedon) writes: In reply to "J. C.'s" inquiry of March 23rd (p. 584), and the notes by Dr. M. Haver and "Aurist" (April 6th, p. 670), though never having had prostatic enlargement, I have noticed for at least forty years that putting my hands in cold water caused a desire to micturate; I have, however, never felt the palmar reflex mentioned.

FATAL LARYNGEAL OBSTRUCTION BY A FISH.

DR. N. A. DYCE SHARP (Nigeria) writes: A few days ago a native woman was catching fish in the river with a basket net, and while transferring the small fry from the net she put one between her lips, her hands being full. The fish apparently gave a jump, and a moment later the woman was seen to fall, struggling to get her breath. Her friends at once opened her mouth and endeavoured to remove the obstruction; they failed, and after five minutes all her convulsive movements ceased. The body was at once brought to the mortuary, with a request for a necropsy; only afterwards did I discover that this was designed to determine whether she was a witch herself or whether she was bewitched, and here I failed! On removing the larynx and as much of the pharynx as possible, I found a small fish, 3½ in. long, wedged firmly down the trachea, with the snout lying transversely between the vocal cords. Minute spines on the dorsal surface and at the border of the gills effectually prevented its extraction upwards, and, indeed, the tail had already been pulled off by the victim's friends. As the width of its head was about 23 mm. and the breadth about 17 mm., the larynx was most completely and exactly occluded. This is well shown in the preserved specimen, which was fixed in an alcoholic solution of perchloride of mercury. A smaller or a larger fish could not have caused so complete an obstruction.

MERITS OF ANTISEPTIC SURGERY.

DR. J. V. DUHIG (Brisbane) writes: I would like to suggest that the holders of the copyright of Lister's *Collected Papers* should publish them in a cheap and handy form in a single volume. The papers are as important a contribution to human thought and achievement as the work of Harvey, Newton, Pasteur, and Einstein, and should be easily available. Compared with Lister's results "aseptic" surgery is a failure; it is the invention of a German much inferior to Lister, and has become a very expensive fetish. Lister could operate with complete confidence of success on acute and chronic abscess, bones, joints, tuberculous abscess of bones, and compound comminuted fractures in a cowshed at the expense of a bottle of carbolic acid. Many young surgeons do not know these facts, and it is time they had the information.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 54, 55, 56, 57, 60, 61, and 62 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 58 and 59.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 95.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

354. Percutaneous Immunization against Diphtheria.

E. LOWENSTEIN (*Wien. klin. Woch.*, February 14th, 1929, p. 193) considers that the immunity produced by the injection of a mixture of toxin and antitoxin, as advocated by some workers, is due to the response of the organism to the toxin, which is slowly liberated, and is therefore not devoid of risk. Another defect of this method appears to be that the immunity is directed against the toxins rather than against the diphtheria bacilli. Löwenstein therefore prepared a detoxicated vaccine by killing unfiltered broth cultures of diphtheria bacilli with formol; he tested its toxicity by subcutaneous injections into guinea-pigs, and found it harmless. Since in both tuberculosis and syphilis extensive lesions in the skin generally appear to protect the internal organs, he attempted to immunize guinea-pigs against diphtheria by rubbing 50 to 300 lethal doses of diphtheria toxin into the shaved skin on two occasions; eight weeks later the subcutaneous injection of a double lethal dose produced no effect, showing that guinea-pigs could be immunized by this means. It was next demonstrated that guinea-pigs could likewise be immunized by inunction with an ointment of detoxicated broth culture through the unbroken skin. The method was then applied to 400 Schick-positive children admitted to a children's home; as a result 70 per cent. became Schick-negative. Estimations of the antitoxin titre of the blood showed that this continued to increase for some months after cessation of the inunction. Löwenstein points out, however, that the value of the Schick test and the antitoxin content of the blood should not be overrated, because they are not a measure of the whole defensive mechanism of the body. By the ultimate test—the morbidity figures in the children subjected to one, two, or three inunctions at fortnightly intervals—the method proved very satisfactory, none of the children treated contracting the disease in spite of the introduction of several infected cases into the home. He concludes that the power of the skin to produce antitoxin in response to inunction has been under-estimated, and recommends that the method should for the present be used in children's residential homes, and should then be applied to immunizing children after the first year of life, as it is effective, simple, and safe.

355. The Clinical Aspects of Venous Pressure.

J. C. PLA (*Anal. de la Fac. de Med.*, November and December, 1928, p. 800), who records his observations in 203 patients aged from 8 to 80, comes to the following conclusions. The normal venous pressure at the bend of the elbow is about 12½ cm. in men, 11 cm. in women, and 7½ cm. in children; it may be affected by various physiological factors, such as effort, digestion, or emotion, which raise it moderately. Certain positions of the head, such as lateral flexion, also increase the venous pressure up to 4 cm. in the opposite arm to that towards which flexion is made. In the normal condition the venous tension in the lower limbs in the saphenous vein at the ankle is less than that in the upper limbs, the average tension being 6 cm. In compensated valvular disease the venous pressure does not undergo any change, but in failing compensation it rises sometimes to a considerable height; when [illegible] hepato-jugular reflux compression [illegible] crease of the venous tension is cat [illegible] of the lower limbs the venous tension falls considerably in the saphenous vein, and sometimes may reach zero. The tension in the saphenous vein is increased in varicosity; when this is due to an abdominal tumour the tension may rise to three times the normal height. In chronic affections of the respiratory system the presence of venous hypertension is often the first sign of the effect of the lung condition on the right heart. In obvious or latent compression of the venous trunks, changes in the venous tension may be a sign of considerable value in diagnosis, as is seen in cases of cervical ribs and mediastinal compression. In spinal anaesthesia the venous tension falls, and this fall may be independent of variations of the arterial pressure. In some therapeutic procedures, such as haemoclasic shock or the administration of amyl nitrite, the venous tension undergoes interesting changes. In haemoclasic shock it falls early, sometimes to a considerable degree, while amyl nitrite, on the other hand, raises it. Changes in the venous pressure in cardiac failure may be of prognostic value, as follows. When the venous pressure remains raised in spite of energetic treatment of the asystole the prognosis is bad. When the venous tension falls and the normal figure is reached the prognosis is favourable.

356. Heart Murmurs.

SINCE innocent precordial murmurs are frequently interpreted as being indicative of cardiac disease, J. H. GIBBES (*Amer. Heart Journ.*, February, 1929, p. 305) has made a special study of such murmurs in 1,166 consecutive cases. The following classification was adopted: organic murmurs, which included those indicative of organic change in the valves; those caused by disease of the aortic arch, those indicating a persistence of embryonic openings between the cardiac chambers; and accidental murmurs, which were independent of structural valvular changes, of congenital heart disease, or of abnormality in the aortic arch. The last were subdivided into intra-cardiac and extra-cardiac, which were clearly demonstrated as being dependent on some phase of respiration. Murmurs were detected in 166 of the cases, of which 127 (75 per cent.) were accidental, thus emphasizing the very great care necessary in diagnosis. Accidental murmurs were noted twice as frequently in females as in males. These murmurs may occur at any age, but were more frequent during the third decade. All the accidental murmurs were systolic, and were most often heard at the base of the heart. In contrast with organic murmurs the transmission of accidental ones is relatively rare. Cardiac hypertrophy is a necessary part of organic heart disease, and was noted in only 11 of the accidental murmurs; in every case the hypertrophy was independent of the murmur. Accentuation of the pulmonary second sound was heard in accidental murmurs of the inorganic type, but not with other types. There was a great preponderance of cardio-respiratory murmurs over accidental ones of other types. Gibbes adds that accidental murmurs are most frequently heard in patients below their optimum weight, and are practically unrelated to the blood pressure and pulse rate. He maintains that other evidence than that afforded by a murmur must be found before a heart is assumed to be diseased.

357. Paratyphoid Fever.

D. HERDERSCHEE (*Nederl. Tijdschr. v. Geneesk.*, January 12th, 1929, p. 132) records observations on 120 cases of paratyphoid fever admitted to the Wilhelmina Hospital, Amsterdam, in the period 1918 to 1926 inclusive, during which 1,560 cases of typhoid fever were admitted. The proportion of children affected was considerably higher than in typhoid fever, 37 (30 per cent.) being below the age of 10 and 83 above; this compares with 303 (19 per cent.) below 10, and 1,257 above, in the case of typhoid. As regards sex, 56 per cent. of the typhoid patients were males, as compared with 52 per cent. of the paratyphoid patients. Only one of the paratyphoid patients died—death being due to broncho-pneumonia following appendicitis in convalescence—as compared with a mortality of 15.4 per cent. in the typhoid patients. No instances of perforation or peritonitis occurred among the paratyphoid cases and only one of intestinal haemorrhage, whereas perforative peritonitis was noted in 2.1 per cent. of the typhoid cases and intestinal haemorrhage in 8.6 per cent. The febrile period was also shorter than in typhoid fever. No examples of thrombosis were seen in patients under the age of 10, among either the typhoid or paratyphoid cases. Above that age thrombosis occurred in about 4 per cent. of each disease. There was only one relapse among the paratyphoid cases, whereas 11 per cent. of the typhoid patients had relapses. There was no difference as regards the incidence of the other symptoms.

358. Cicatricial Sequels of Visceral Syphilis.

GOUGEROT (*Paris Méd.*, March 2nd, 1929, p. 209) draws attention to the comparative frequency of recurrences of nervous symptoms after the apparent cure of syphilitic conditions. Residual visceral sclerosis causing persistence of the anginal pain is, he thinks, more widely recognized than, for instance, the recrudescence of tabetic pains in a patient whose syphilis has become inactive, such pains being the result of congestion in the sclerosed areas which is brought on by gastro-intestinal disturbance or other causes. He reports two cases. A woman, aged 43, first attended hospital for major epileptic attacks which had lasted five years. The Wassermann reaction was positive, and intensive antisyphilitic treatment resulted in the cessation of attacks in four months. She remained free from attacks, except for six, which followed various possible

exciting causes such as alcoholic excess, intercurrent illness, or the antisyphilitic treatments by injection, until five years later, when very frequent attacks recommenced in spite of steady improvement in the Wassermann reaction, and continued until her death in a street accident. A man, aged 36, first showed signs of neurosyphilis (optic neuritis without tabes) fourteen years after the probable primary infection. Active treatment was given and the Wassermann reaction became negative, but four years later he had a first attack of Jacksonian epilepsy. Treatment was continued and the Wassermann reaction remained negative, but in another two years' time symptoms of general paralysis appeared; malarial treatment produced a clinical cure, confirmed by examination of the cerebro-spinal fluid. The next year the Jacksonian epilepsy recurred, and attacks have followed almost daily since then. Gougerot considers that such epileptic relapses are due to irritative lesions of a non-specific nature, and are in fact the result of cicatricial relics which antisyphilitic measures are powerless to remove. He stresses the importance of gastro-intestinal disturbances as capable of producing congestion in the cicatricial areas.

359. An Epidemic of Trichinosis.

E. P. MCDONALD and K. C. WADDELL (*Journ. Amer. Med. Assoc.*, February 9th, 1929, p. 449) record an epidemic of 43 cases which occurred at Albany, New York, following the consumption of diseased pork. The ages of the patients ranged from 3 to 42; 31 (88 per cent.) showed eosinophilia of 41 per cent. or less, 4 (11 per cent.) showed no increase of eosinophils, and in 8 no blood counts were made. In patients with a concurrent infection such as pneumonia there was no eosinophilia. Although patients with cerebral symptoms and signs may show the parasites in the spinal fluid, these are not consistently present. There is no specific remedy, but drastic catharsis is beneficial in the early stage, since it aids in ridding the intestinal tract of parasites. The blood sugar was low in all the patients, which may be explained either by impairment of glycogen due to the presence of myositis or to increase of sugar consumption through involvement of the muscles.

360. Laryngeal Diphtheria complicated by Thymus Hypertrophy.

F. SCHWENTKER (*Arch. of Pediat.*, December, 1928, p. 733) records a fatal case of laryngeal diphtheria treated by antitoxin and intubation, the infection being complicated by an enlarged thymus. Cultures of the throat yielded Klebs-Loeffler bacilli, and at the necropsy slight diphtherial necrosis was detected in the throat and larynx. The thymus was found closely overlying the trachea; it was much larger than normal and weighed 22 grams. The other organs were normal, except for a cyst in the right ovary. Schwentker has been unable to find a similar case in the literature.

Surgery.

361. Acute Haematogenous Infection of the Kidney.

W. LINDER (*Amer. Journ. Surg.*, February, 1929, p. 175) is convinced that this infection is generally carried to the renal cortex by the blood stream, the staphylococcus being the most frequent causative factor and the streptococcus ranking second. Acute unilateral haematogenous infection of the kidney occurs as a result of the blocking of the minute blood vessels of the renal cortex by microbic emboli, the resistance of this organ being lowered by some anatomical anomaly or an increased functional demand, as in pregnancy, which causes the glomeruli to fail to function. The progress of the disease and its severity depend on the resistance of the individual. Mild cases may be treated palliatively with rest in bed, the forcing of fluids, and the administration of urotropine, though frequently a second attack occurs and necessitates surgical treatment. The surgical procedure depends on the extent of suppuration and the location of the lesions, and also on the condition of the other kidney. In the fulminating types prompt nephrectomy affords the only chance of cure; nephrotomy is not successful. Where there are small cortical or subcapsular abscesses decapsulation has been practised with excellent results, and should be the operation of choice where the condition of the second kidney is doubtful. Release from its encasement and proper drainage will often cure this type of kidney infection. When suppuration has extended through the capsule of the kidney into the fatty tissues, causing a perinephritic abscess, the establishment of drainage will often effect a cure. Linder emphasizes the importance of early diagnosis and treatment, since delay may cause sepsis and involvement of the other kidney. It is invariably found that some mild or severe infection, such as influenza, tonsillitis, pharyngitis, a boil, or a carbuncle, has antedated the kidney infection. The symptoms of this condition are nausea and vomiting, with fever ranging from 102° to 105° F., a rapid pulse, severe prostration, with pain and tenderness in in the abdomen, most often the right half. Pressure at the costo-vertebral angle will elicit exquisite tenderness in early cases, but later, when the capsule has perforated by extension of the suppuration, the tenderness disappears. Urine examination may reveal nothing abnormal. The disease is most prevalent in the third and fourth decades of life.

362. Primary Carcinoma of the Appendix.

J. SELINGER (*Annals of Surgery*, February, 1929, p. 276) reports 34 cases of carcinoma of the appendix operated on during the past eight years. The average age of the patients was 34, the majority of cases being in the third decade of life; 82.4 per cent. were females. In every case the operation was undertaken on a diagnosis other than carcinoma, and this condition was never suspected prior to operation. In all cases the growth was primary in the appendix; in 28 it was situated at the tip, in 5 at the base, and in one midway between tip and base. Of the 5 cases in which it affected the base, one showed penetration of the serosa, and in one there was a metastasis in the meso-appendix; they were all of the columnar-cell type, or gelatinous adeno-carcinoma, which may occur at any age and is nearly always benign. The author remarks that it has been said that these carcinoids result from proliferation of the intranervous argentaffin cells of the neurocrine type which pile up in the nerve fibres, finally rupture their sheaths, and infiltrate the intestinal tissue of the neuroma and then that of the submucosa. In this form of carcinoma there are no signs or symptoms of sufficient distinction to warrant a pre-operative diagnosis, and the surgeon is usually surprised when the pathologist reports that the appendix removed shows a carcinoma or carcinoid at the tip.

363. Delayed Traumatic Intracranial Haemorrhage.

E. M. HAMMES (*Minnesota Med.*, February, 1929, p. 86) believes that delayed traumatic intracranial haemorrhage is more common than is usually thought. He recognizes two large groups, the first including cases in which the hemorrhage occurs within the cerebral substance, and which are classified as traumatic late apoplexy. In the second group the haemorrhagic lesion is extracortical; it may be either extradural and due to a ruptured meningeal artery, or intradural, when it is usually of venous origin and gives rise to a true chronic subdural haematoma. In the traumatic late apoplexies the time interval between the trauma and the delayed cerebral symptoms varies from several hours to days and even months; the interval in the subdural haematomas is usually longer than in the extradural type. Hammes gives details of several cases, and warns that with a history of even slight head injury, when there are subsequent cerebral manifestations, the possibility of such delayed haemorrhage must be seriously considered. The clinical course is fairly typical, the symptoms being rapidly increasing intracranial pressure, indicated by severe headache and drowsiness; brachycardia; vomiting; localized muscular twitchings; Jacksonian convulsions; and incomplete hemiplegia, more marked in one extremity. The spinal fluid in uncomplicated cases is under increased pressure; it is clear and contains no evidence of blood. Repeated lumbar punctures are of definite therapeutic value and will frequently tide over an emergency, giving opportunity for further investigation. Decompression is required as soon as the diagnosis is made and localizing symptoms have become manifest.

364. Haemorrhoidectomy.

W. F. BURROWS and E. C. BURROWS (*Med. Journ. and Record*, February 20th, 1929, p. 216) point out that underlying the symptoms of pain, discomfort, discharge, itching, bleeding, or prolapse, which a haemorrhoidectomy should aim at eliminating, are in many instances the tight anal canal and constipation or incomplete evacuation. A less radical operation than the one usually employed is described, giving a minimum of trauma and an easy convalescence. The bowel is completely emptied by castor oil on the night of the second day before the operation, and on a restricted diet bowel movement is controlled until the second or third post-operative day, when an enema is given. Under gas and oxygen anaesthesia the sphincter is stretched and each mass of haemorrhoids is drawn downward without putting tension upon the mucosa above. The base is clamped parallel to the anal canal on each side of the median line posteriorly, and the mucosa is drawn into the clamps from the lateral walls as far as this can be effected easily. After cutting away the clamped tissue the blood supply is cut off by ligatures, and the tissue is brought together with two or three locked No. 1 catgut sutures. The clamp is loosened and tabs are removed, the area being closed by continuing the original suture. In

cases where the anal canal is contracted it is best to stretch the sphincter muscles only moderately, and then through an analscope to cut the external sphincter in the posterior median line. The authors found that there were no recurrences after this modified technique, and the resulting unobstructed rectum rectifies many cases of constipation with incomplete bowel emptying.

365. Pneumococcal Peritonitis.

According to D. C. ELKIN (*Arch. of Surg.*, February, 1929, p. 745) pneumococcal peritonitis develops as a secondary complication of pneumonia or appears as a primary infection. It is comparatively rare and has a high mortality rate, more than 50 per cent. of cases ending fatally. The primary variety occurs most frequently in young girls, and it is suggested that it is due to the passage of bacteria through the Fallopian tubes to the pelvis. It does sometimes, however, occur in boys and men, but it is possible that these cases are really secondary to an undiscovered focus elsewhere in the body, clinical evidence being strongly in favour of a genital theory of infection. Secondary peritonitis develops from embolic implantation of the pneumococci which are present in the blood stream of a patient suffering from pneumonia, and are passed by direct extension through the diaphragm to the abdominal cavity. The infection is generally evident in the upper part of the abdomen and on the side adjacent to the affected lung. The prognosis depends on the severity of the infection and the individual susceptibility rather than on any form of treatment. Recovery in the secondary cases is rare, as patients develop septicaemia from an overwhelming peritonitis, though in less severe cases the infection may be walled off by the protective mechanism of a plastic exudate. If the peritoneum is only locally involved recovery after drainage will usually ensue, but not if there is diffuse peritoneal involvement.

366. Remote Results of Fractures of the Femur.

R. BESTELMEYER (*Deut. Zeit. f. Chir.*, March, 1929, p. 240) investigated the results of treatment of 95 cases of fracture of the femur due to gunshot wounds received in the world war. His conclusions were as follows. (1) The end-results were unfavourable. The most striking facts were the extraordinary frequency of damage to the knee-joint (80.9 per cent.); the frequency of chronic osteitis (25 per cent.); the *marked shortening of the limb (4.8 per cent.)*; and the diminished power of earning a livelihood (58 per cent.). Damage to the hip-joint, which was noted in 19.1 per cent., was much less important. Damage to the ankle-joint could always be avoided by careful treatment. (2) The view of Franz that German surgeons employed primary amputation too seldom in fractures of the femur was confirmed by the investigation of Bestelmeyer, who saw many cases which would have done better with this operation. (3) No opinion could be expressed as to the value of individual methods of treatment because most of the wounded had been treated in different hospitals and by different medical officers with a variety of methods. (4) In order to obtain better results in future Bestelmeyer adopts the suggestion of Franz that *fractures of the femur should be treated in special hospitals* behind the front, and that the frequent change from one hospital to another should as far as possible be prevented. In most of Bestelmeyer's cases this frequent transfer had occurred, with prejudicial effects to the patient.

367. Amoebic Abscess of the Lung.

A. PELLE and LE BARON (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, February 18th, 1929, p. 235) record a case of an amoebic pulmonary abscess, and point out that amoebiasis is not unusual. It is becoming more and more frequent in reports from various clinics, because it has increased since the war, especially among young soldiers who are stationed in Morocco or Syria. Sometimes there are intestinal symptoms, and *occasionally liver or lung complications*; the development of the condition often simulates a tuberculous condition of the lung, which can only be eliminated by frequent examinations of the sputum. The typical symptoms are the cough, a more or less acute pain in the chest, and a chocolate-coloured sputum in which amoebae may be seen microscopically. Radiological examination shows extensive shadows with well-defined outlines. If neglected the patient will die, but the intensive administration of emetine quickly arrests the development of the disease. This treatment may be combined with pneumothorax, which obviates any danger of a severe haemorrhage and promotes healing of the abscess.

368. Adenoma simulating Prostatic Enlargement.

L. PHÉLIP (*Lyon Méd.*, February 3rd, 1929, p. 130) records the case of a man, aged 32, examined on account of incontinence of urine; prostatic hypertrophy was suspected, but on rectal examination no enlargement was felt. On catheterization after micturition 80 grams of residual urine was obtained. Cystoscopy revealed some oedema at the urethral opening, which had a gaping appearance. Immediate improvement followed diathermy of the neck of the bladder, though the residual urine remained as much as 30 grams. The patient returned five years later with recurrence of the symptoms, and cystoscopy now showed at the neck of the bladder a small object which impeded the opening and shutting of the urethral orifice. This was removed, and histological examination of the fragments showed adenomatous tissue with no sign of malignancy; the patient made a good recovery with disappearance of the residual urine. Phélip remarks that he has operated in another similar case by the suprapubic route with the same final result, but recovery was less rapid. He adds that such cases are of interest as showing that a considerable amount of residual urine may exist where no palpable prostatic enlargement can be found.

369. Chordoma of the Maxilla.

S. RUBASCHOW (*Zentralbl. f. Chir.*, January 19th, 1929, p. 137) reports a case of tumour in a child, twenty-four hours old, projecting from and covering the mouth; it was attached by a thin pedicle to the alveolar margin at the middle of the upper jaw. On microscopic examination the tumour was recognized as a chordoma. The report is accompanied by a drawing and photograph of the tumour, but the dimensions are not given.

Therapeutics.

370. Treatment of Nephritis and Nephrosis with Oedema.

IN the treatment of nephritis and nephrosis with oedema the aim of E. G. BANNICK and N. M. KEITH (*Journ. Amer. Med. Assoc.*, December 22nd, 1928, p. 1944) has been to employ measures that induce the excessive amount of the tissue fluid to start travelling toward the blood, to be ultimately excreted by the kidney; they discuss such treatment in 100 cases, which were arranged in five groups: acute diffuse glomerulonephritis; acute renal insufficiency; subacute or chronic glomerulo-nephritis; chronic nephrosis; and chronic nephrosis of the mixed type. The treatment of each group is fully described, but, generally speaking, the method found most satisfactory was the combined use of suitable diets with low salt and fluid contents, and one or more of the various diuretics. The diet should provide sufficient calories and the amount of protein be adjusted to meet the conditions. When azotaemia exists reduction to a daily intake of 40 grams of protein may be necessary, while in cases of nephrosis adequate, but not excessive, amounts are advisable. The best combination of diuretics was found to be ammonium nitrate and organic mercury compounds. Xanthine preparations such as theophyllin-ethyl-endiamine, given by the mouth in doses of 0.6 to 1 gram, were also effective. The diuretic period continues for two to six weeks, and the loss of fluid may amount to 80 lb. During this time there is often an immediate tendency to gain in weight. This tendency to retain fluid and salts after rapid fluid loss emphasizes the importance of a low salt and water intake in preventing rapid accumulation of fluid in resistant cases of oedema. Elimination of the oedema seems to benefit the whole organism, often permitting patients to live normal lives and to build up resistance to infections. Future treatment when the patient is free from oedema must be considered. The tolerance for water and salts must be gauged, and, if it is low, the diet must be continued indefinitely; in resistant cases periodic prolonged treatment with diuretics may also be necessary. Foci of infection should be eradicated. Exact diagnosis is important. In acute renal lesions recovery is often complete. In most cases of chronic nephrosis the disease can be arrested and the patient enjoy comparatively good health. Death usually results from an infection rather than renal insufficiency. Arrest of subacute or chronic glomerulo-nephritis is rare; most cases run a progressively downward course, and death is usually due to renal insufficiency.

371. Gold Salts in Chronic Rheumatism.

J. FORESTIER (*Bull. et Mém. Soc. Med. des Hôp. de Paris*, March 11th, 1929, p. 323) explains how, in 1928, his attention was drawn to the fact that it might be possible to treat some cases of chronic rheumatism with certain preparations of gold which have been used with success in the treatment of tuberculosis. In 1914 Moellgaard pointed out that gold thiosulphate had a specific action on the tubercle bacillus and tuberculous tissues. His preparation (sanocrysin) has been found of definite value in some cases of pulmonary tuberculosis. There is a similarity between the clinical course of some cases of chronic rheumatism and cases of tuberculosis—particularly the continuous fever, the general condition of the patient with anaemia and leucocytosis—and it was therefore thought possible that the gold preparations used for

tuberculosis might be of value in cases of rheumatism. Gold thiosulphate was therefore tried, and also a preparation of sodium aurothioproponal sulphonate. This substance is a white powder, soluble in water, which can be injected intramuscularly and is easily absorbed and very slightly toxic. This preparation has been tried in cases of chronic polyarticular rheumatism with thickened synovial membrane. The dosage used in these cases was 25 cg. of allochrysine given intramuscularly at intervals of five to seven days; 11 women and 4 men were treated during a period of ten months: 5 benefited markedly, justifying a hope of permanent cure; 5 others were definitely improved and continue to make slow progress; 2 more had insufficient injection to show much improvement; and 3 other cases could not be traced. In no cases have the symptoms been aggravated, and the improvement has been manifested both in the local and general condition of the patients. In cases of rheumatism of the joints the thickening of the synovial membrane and the fluid have markedly decreased or disappeared altogether, with considerable relief of pain, especially on movement. It appears, therefore, that this method of treatment is of definite value in cases of severe arthritis deformans.

372. Insulin in Primary Wasting.

P. RUSSO (*Studium*, February 20th, 1929, p. 64) recommends insulin as a good therapeutic agent for states of wasting which are not due to serious organic disease and records ten cases so treated. The appetite always increased and there was gain in weight. Not only was more food taken at a meal, but an addition to the number of meals was welcomed by the patients. With the increase of appetite and weight went a feeling of well-being, and the general condition was notably improved. In one case the patient had suffered for many years with functional disturbance of the gastro-intestinal canal. After one month's treatment with insulin not only did she put on weight, but this particular trouble entirely disappeared. Small doses only are needed to determine the increase in body weight and the general improvement. It is not necessary, as in cases of diabetes, to limit the intake of carbohydrate, and therefore all food can safely be increased according to the patient's appetite. The dosage varied, but, as a rule, 5 to 10 units were given at the beginning, and 20 to 25, with a maximum of 30, at the end of the treatment. The injections may be intramuscular or subcutaneous, and are made ten minutes before a meal containing an adequate amount of carbohydrate in the form of cereals, approximately 2 grams for every unit of insulin. The treatment is continued for about three weeks.

373. Therapeutic Uses of Bacterial Filtrates.

G. BUCHANAN (*Journ. Med. Assoc. of South Africa*, January 26th, 1929, p. 37) records results obtained with bacterial filtrates, as introduced by Besredka, in the treatment of several pyogenic infections. The filtrates were made from cultures killed by heat after incubation for ten days; they were found to exert an attenuating and inhibitory action on bacteria and a non-toxic action so far as animal inoculation was concerned, but they produced severe protein shock when injected into human beings, and consequently are considered unsuitable for subcutaneous administration. Their mode of application was by wet gauze dressings in skin infections, irrigations of septic wounds, and by spraying or as a mouth-wash in nose and mouth conditions. Since they were used successfully in chronic suppurative conditions in which other treatment had failed, the method was tried in some acute pyogenic infections and severe injuries. Notes of cases are given in which the local application of filtrates proved efficacious where other treatments had previously failed, including cases of septic indolent ulcer, chronic suppuration, boils, sycosis, erysipelas, nasopharyngitis, suppurative perichondritis, pansinusitis, acute osteomyelitis, wounds, compound fracture, pyorrhoea, stomatitis, and suppurating tuberculous cervical glands. Besides arresting septic processes, bacterial filtrates appear to stimulate the development of healthy granulating tissue. Buchanan considers that the cases recorded point to an undoubted therapeutic value in pyogenic infections.

374. Treatment of Arthritis.

F. C. HALL (*New Eng. Journ. Med.*, February 21st, 1929, p. 369) reports the results of treatment in 89 cases of arthritis averaging five years in duration; no focal infection was discovered and only appeared to be a possible factor in six. In twelve cases the arthritis was of the atrophic type, and treatment aimed at improving the general health and correcting any abnormality, such as fatigue, dietary or endocrine deficiencies, constipation, and bad body mechanics. The general measures adopted were: rest in a recumbent position which lasted from a few hours more than usual to confinement to bed for several days or weeks; a diet high in vitamins and salts and sufficient in calories; sunshine; and exercise according to the patient's condition. Most of the patients were found to have some dietary or endocrine deficiency; correction of this relieved the fatigue and improved the arthritis. Hall recommends a daily diet of one quart of milk, extra butter and cheese, two eggs, lettuce, spinach, cabbage or beans, and plenty of fruit, with whole white bread, whole-grain cereals, and cod-liver oil, with the addition of calcium lactate to supplement any insufficiency of calcium in the milk and green vegetables. On these lines he obtained in 59 cases arrest of the disease, or such marked improvement that arrest appeared certain; while 25 did fairly well. Such general measures are held to be so important as to constitute a prerequisite to any high degree of success in treating arthritis. W. M. BARTLETT and E. SUNESON (ibid., p. 375) remark that the salts of ortho-iodoxy-benzoic acid do not cure arthritis, though the ammonium salt, when injected intravenously in large doses, relieves the pain and muscle spasm. They advocate active motion of the joints, regardless of the pain and muscle spasm, together with vigorous and deep muscle massage.

Disease in Childhood.

375. Chronic High Blood Pressure in Children.

E. FAERBER (*Monats. f. Kinderheilk.*, January, 1929, p. 148) considers that blood pressure estimations in children have not received as much attention as they deserve because unless repeated observations are made the values obtained may be influenced by so many nervous and other physiological factors as to be unreliable. It is generally acknowledged, however, that the blood pressure gradually rises from birth to puberty with increase in age, weight, and height, the average value in infancy being 80 to 85 mm. of mercury and 110 to 115 mm. at puberty. Low pressures have been observed in scarlet fever, diphtheria, tuberculosis, lymphatism, asthma, and diabetes. Transient rises in blood pressure occur in neuropathic children, in dyspnoea, and in acute nephritis. The author has hitherto only observed a continued and marked hypertonia in the rare cases of chronic interstitial nephritis. Of one case, however, occurring in a boy aged 12, ultimately diagnosed as orthostatic albuminuria, which Faerber had under observation for two and a half years, he records the following: (1) onset of illness with cerebral symptoms (choked disc, vomiting, headache) which, however, subsequently subsided without further evidence of increased intracranial pressure; (2) continuous raised blood pressure (170 to 190 mm. for one year), retinitis, albuminuria; (3) gradual disappearance of symptoms, fall in blood pressure to 125, discs becoming normal. Renal function tests throughout showed that there was no renal insufficiency and that the albuminuria was of the orthostatic type. In view of these observations and the records of others, ophthalmologists and physicians, Faerber considers that the term hypertonic retinitis should be substituted for albuminuric retinitis. He suggests that further records reveal that cases of chronic interstitial nephritis in children are preceded by comparatively transient symptomless periods of raised blood pressure, and that, conversely, the ultimate prognosis in the case described may not be so good as the present condition might lead one to anticipate.

376. A Clinical Study of Enuresis.

A. BLEYER (*Amer. Journ. Dis. Child.*, November, 1928, p. 989) presents his observations on 129 boys and 123 girls, extending over a period of three years. He concludes that certain factors, such as enlarged or diseased tonsils and adenoids, the male prepuce, vaginitis, pyelitis, a neurotic constitution, and lack of discipline, commonly held accountable for enuresis, have no such etiological relationship. He defines this condition as a disturbance of micturition, in which the physiological control of the brain is blocked by stronger stimuli which have to do with the nervous mechanism of the bladder; this loss of physiological control does not appear to lie in the brain. In the treatment of the condition he discusses the physiology of micturition and gives prominence to Young's discovery that the opening of the sphincter of the bladder is not an act of inhibition, but is brought about by the muscles of the trigone. There is some evidence that the innervation of the trigone is more or less independent of that of the bladder. The author finds that atropine is a specific remedy and claims cure with it in 80 per cent. of his cases. The dosage should be as near the margin of overdosage indicated by mydriasis and flushing as possible. He recommends a solution of only 0.25 grain to the ounce, so as to permit of a closer adjustment of the drug to the individual need. He also advocates massage of the bladder, which is performed by inserting the finger into the rectum and touching the trigone; the pressure should be light and need not be continued for more than a moment.

377. Prognosis of Tuberculosis in Children.

G. J. HUET (*Nederl. Tijdschr. v. Geneesk.*, December 15th, 1928, p. 615) states that, apart from cases of "open" tuberculosis, the prognosis of tuberculosis in children is not unfavourable, as is shown by the following statistics. Of 271 children who had been treated in the Hoog-Blaricum Sanatorium at Amsterdam in the period 1912-18, it was found that 67.9 per cent. were in a satisfactory and 23.7 per cent. in an unsatisfactory condition, while only 8.4 per cent. had died. Similarly, Laird found that among 107 children twelve years after their discharge from the Nopenning Sanatorium, Minnesota, 72 per cent. were in a good and 13 per cent. in a bad condition, and 7.5 per cent. were dead. Poelchau found that 93.4 per cent. of the children discharged from a sanatorium at Charlottenburg showed no marked signs eight years later. Huet has recently investigated the condition of 1,257 children treated at the Hoog-Blaricum Sanatorium between 1919 and 1926. He found that the best results had been obtained in patients with peritonitis and pleurisy, of whom 100 and 93.8 per cent. respectively were in good condition in 1928. On the other hand, 84.5 per cent. of the cases of progressive tuberculosis terminated fatally.

Obstetrics and Gynaecology.

378. Tubal Pregnancy simulating Strangulated Hernia.

C. HEITZER (*Zentralbl. f. Chir.*, February 23rd, 1929, p. 461) describes a case of extrauterine pregnancy in which the symptoms caused a diagnosis of strangulated hernia to be made. A woman, while trying to lift a heavy weight, collapsed suddenly with severe pain in the lower abdomen, and noticed for the first time a swelling in the right groin. There was also slight haemorrhage from the vulva; the last regular menstrual period had occurred fifty-three days previously. The patient improved so rapidly with rest in bed that on the third day she returned to work, but the pain returned; an unsuccessful attempt to reduce the "hernia" was made. On admission to hospital she reported that there had been no passage of faeces nor flatus for two days; hiccup was present, but no vomiting. In the right groin there was a smooth, tense, irreducible swelling as large as an egg; it was not very tender, and appeared to be an incarcerated hernia. On opening the hernial sac it was found to be filled with blood-clot, but contained no bowel. Next day the patient was very collapsed and much more anaemic; the pain persisted, and the abdominal wall was rather tense and very tender. There was dullness in the left hypochondrium and above the pubes. Hiccup and slight bleeding from the vulva continued. The uterus was enlarged and somewhat soft, the posterior vaginal fornix being obliterated. The increasing abdominal tenderness and the genital haemorrhage led to a suspicion of extrauterine pregnancy, and a laparotomy revealed a ruptured left tubal pregnancy. The true pelvis contained blood-clot and a small amount of fluid blood. The left tube was resected, the blood-clot was removed, and the abdomen was closed. Progress was uneventful until two weeks after the laparotomy, when thrombosis of both internal saphenous veins occurred; a fortnight later the patient was discharged cured.

379. The Vomiting of Pregnancy.

J. P. GARDINER (*Journ. Amer. Med. Assoc.*, December 22nd, 1928, p. 1937) considers that the vomiting of pregnancy is a self-limiting disease, and that [illegible] with it are different from those of ot[illegible]is, an involuntary muscle, acts in accordance with the law of involuntary muscles—that is, independently of central control. It is well known that a relationship exists between the genital and intestinal tracts: thus menstruation stimulates the intestines, causing looseness of the bowels. The time of greatest activity of the chorion corresponds with the time of the greatest frequency of the vomiting. Gardiner believes that a protective substance from the zygote influences the genital organs and, penetrating to the intestinal tract, reduces the activity of the intestines (in order to protect the ovum) to such an extent as to simulate partial or complete intestinal obstruction; this in turn gives rise to reverse peristalsis, thus causing the nausea and vomiting. The human being, because of her upright position, is the only mammal subject to the vomiting of pregnancy. Experiments have shown that the pathological changes in this disease differ little from those of inanition or starvation, and the immediate cause of death is probably exhaustion. Treatment is considered under three heads: the limiting of the vomiting, supportive treatment, and the induction of abortion. The vomiting is limited by two methods. In one the genital and intestinal tracts are separated as far as possible, and for this the inverted ventral method is recommended, the patient lying face downward as much as practicable with the shoulders above the level of the buttocks; in the other the sensitiveness of the intestines is reduced by the use of sedatives. The necessity of food other than carbohydrate for the support of the organism seems less urgent than was formerly believed. As regards dextrose and other injections, Gardiner believes that enteroclysis is safer, and a more rational guide to the amount necessary than intravenous injection or hypodermoclysis. If induction of labour becomes necessary the method adopted depends on the dilatability of the cervix and the size of the foetus.

380. Avertin Anaesthesia in Gynaecology.

M. RODECURT (*Narkose und Anaesthesie*, February 15th, 1929, p. 39) records his observations on 130 abdominal and 20 vaginal operations performed under avertin anaesthesia at the Carlsruhe gynaecological clinic. The total dosage ranged from 12 to 12.6 grams of avertin, which was given by rectal injection. Rodecurt's conclusions are as follows. Avertin anaesthesia represents a considerable advance, its chief value consisting in the avoidance of psychical shock. The amount of ether subsequently required is considerably smaller; post-operative vomiting, post-anaesthetic bronchitis, and pneumonia are decidedly rarer than after other anaesthetics. The long subsequent sleep helps to diminish the pain following the operation. The patients themselves are very pleased with the method. Their amnesia usually extends back to the time of the rectal injection, so that they scarcely remember even the addition of ether. The dangers are very slight if complete anaesthesia is avoided and avertin is regarded merely as the basal narcotic.

381. Diathermy in Female Gonorrhoea.

P. PEDICONI (*Urol. and Cut. Rev.*, February, 1929, p. 75) states that clinically it has been shown that there is always a remarkable diminution or cessation of the gonorrhoeal discharge from the urethra on the supervention of fever. The discharge reappears on cessation of the fever only to disappear again when it returns. This clinical observation confirms the statement that the gonococcus is thermolabile not only *in vitro* but also *in vivo*. It is therefore logical to attack it by the application of heat. Pediconi has recently treated numerous cases of subacute and chronic gonorrhoea in women by diathermy with good results. The following precautions, however, are necessary: (1) It must be absolutely certain that the patient is not pregnant. (2) The treatment should be started with short sessions and moderate dosage. Pediconi begins with 1½ amperes for fifteen minutes and gradually increases the amperage to 3 with a duration of forty-five minutes. (3) The metallic plate must be perfectly in contact with the sacrum and pubis to avoid burning. As a rule the patient does not complain of any pain during the application, but there is only a feeling of more or less intense heat in the organs through which the current is passing. Complete recovery usually follows ten applications.

382. Dermoid Cyst of the Ovary.

VILLARD and R. LABRY (*Lyon Méd.*, February 17th, 1929, p. 185) record a case in which at operation a large ovarian cyst was found containing sebaceous material and hair, and the rather less usual finding of a mandibular arch with three rudimentary teeth and one completely formed tooth. Before the operation the tumour was extremely mobile and could be pushed easily from one flank of the patient to the other without any impulse being communicated to the uterus. This mobility was due to the presence of a long pedicle (20 cm.), which was twisted one and a half times. An *x*-ray examination before the operation revealed nothing within the shadow of the tumour except a very faint curvilinear shadow, which was hardly noticeable. It is questioned whether the lack of definition was due to the constitution of the embryonic material or to the coincident presence of sebaceous material.

383. The Alkaline Reserve in Gynaecological Operations.

C. G. GARCÍA and O. F. DIAZ (*Arch. de med., cir. y esp.*, February 23rd, 1929, p. 249) studied the alkaline reserve by van Slyke's method in thirty gynaecological operations with the following result. As a general rule there was a low alkaline figure after the operation, possibly due to the toxic action of the anaesthetic on the liver. Of twenty-eight patients who had been anaesthetized with ether sixteen showed acidosis. In two cases in which chloroform was employed the alkaline reserve was fairly low, and the same result was found in four in whom spinal anaesthesia had been used.

Pathology.

334. Variations in the Cardiac Measurements.

D. SCHERF and E. ZDANSKY (*Wien. Arch. f. Innere Med.*, January 20th, 1929, p. 399) have made numerous orthodiagraphic measurements of the human heart after intravenous injections of atropine and of adrenaline and inhalations of amyl nitrite. They find that in normal persons changes occur in the systolic and diastolic cardiac diameters under the influence of paroxysmal tachycardia and the administration of atropine, adrenaline, or amyl nitrite. The intravenous injection of 0.002 gram of atropine was found to increase the frequency of the heart's action and to diminish the systolic and diastolic cardiac diameters. This reduction in volume was always more obvious as tachycardia increased. In one woman an existent tachycardia, due to paroxysmal attacks of auricular flutter, trebled the flow of blood into the auricle, but the cardiac diameters were reduced only to the extent of 12 per cent. After the intravenous injection of 0.05 cm.³ of a 1 in 1,000 solution of adrenaline a reduction in the volume of the heart was observed in half the cases. No enlargement of the heart was ever detected, although on one occasion the blood pressure rose to 210 mm. of mercury. The absence of change in the cardiac diameters thus demonstrated indicated that the positive inotropic action of adrenaline outweighed the cardio-dilator effect of the rise in blood pressure. In certain cases the reduction in the cardiac diameters was found to persist, together with a diminution in the excursions of the cardiac borders, which was connected probably with a diminution of cardiac output. After the inhalation of amyl nitrite the cardiac diameters were very definitely reduced, though less than would have been expected theoretically on the basis of the sum total of diminution in effective power. In all cases the reduction in frequency of systole was parallel with the diminution in heart volume; this averaged only 10 per cent. On one occasion this diminution amounted to a systolic reduction of 13.5 per cent. in the original breadth of the curves. Any actual change in the volume of the cardiac output could not be deduced from the curves.

385. Bacteriology of Otitis Media.

J. H. FISHER (*Journ. Infec. Dis.*, January, 1929, p. 33) has made a bacteriological study of 46 cases of acute otitis media, with or without accompanying *mastoiditis*. In 4 cases the lesions were bilateral. Cultures taken from the ear or the mastoid revealed the presence of *Streptococcus haemolyticus* in 74 per cent., of staphylococci in 16 per cent., and of pneumococci in 6 per cent. In 32 of the 37 cases in which *Strep. haemolyticus* was found this organism was present in pure culture. An attempt was made to reproduce otitis media in rabbits with fifteen strains of the streptococci and pneumococci recovered from the human patients. In each experiment three rabbits were employed. The first rabbit, on the day prior to inoculation, had its nasal passages swabbed with a 50 per cent. aqueous solution of phenol; the second rabbit was treated similarly; the third rabbit received no preliminary preparation. Twenty-four hours later the first and the third rabbits were given an intranasal inoculation of 1 c.cm. of a twenty-four-hour Huntoon's dextrose broth culture of the organism to be tested, 0.5 c.cm. being delivered into each nostril. The second rabbit received no culture. The effect of the phenol swabbing was to set up an acute inflammatory reaction, lasting for about two days. None of the rabbits of the second or third series, which received swabbing alone or culture alone, died. On the other hand, of 15 of the rabbits that were swabbed with phenol and subsequently inoculated with culture, 11 died; of these, 10 had been inoculated with *Strep. haemolyticus*, and one with a pneumococcus. At the necropsies on these animals acute purulent paranasal sinusitis and acute otitis media were found in every instance; in some of the animals pleurisy, empyema, lobular pneumonia, lung abscesses, pericarditis, and septicaemia were also present. Judging by the staining characteristics of the cells, it appeared that the exudate in the paranasal sinuses was older than that in the middle ear. This observation, among others, leads the author to the conclusion that otitis media is not a blood-borne infection, but is due to direct extension from the nasal passages.

386. The Reticulo-endothelial System in Chronic Metallic Poisoning.

G. BIANCHINI (*Haemato'ogica*, Fasc. I, 1929, p. 33) found that in spite of prolonged administration by the mouth to rabbits and guinea-pigs of the salts of mercury, arsenic, and copper, he was unable to obtain a haematological picture indicating each of these intoxications. Leucocytosis was always constant at the onset, and lymphocytosis, though characteristic of lead poisoning, was also found in poisoning by the compounds and vapour of mercury; monocytosis was present in lead, mercury, and arsenical poisoning, while eosinophilia was of inconstant appearance in copper poisoning. None of these findings, therefore, could be regarded as specific. On the other hand, the reticulo-endothelial system was definitely modified in its structure and composition as the result of poisoning by *lead*, mercury perchloride, and arsenic; less decidedly so by the vapours of mercury; and hardly at all by copper sulphate, even when its action was prolonged. The reaction was shown by an increase in the surface of the syncytium, and by the detachment and mobilization of its elements. This indicates that even inorganic poisons after introduction into the system in a state of solution become fixed in the mesenchyma in a colloidal form. Bianchini thinks that these modifications should be regarded as the morphological expression of acquired organic resistance.

387. Bacterial Flora of the Vagina during Pregnancy.

G. V. SEGRE (*Giorn. di Batteriol. e Immunol.*, January, 1929, p. 26) has examined the vaginal flora of 100 gravid women. Material for examination was taken from the vaginal wall by means of a platinum loop introduced through a speculum. Direct smears were made, and numerous tubes of culture media were inoculated; these were incubated under both aerobic and anaerobic conditions. In the case of 37 women in the first three months of pregnancy, Döderlein's bacillus was found in 20, staphylococci in 4, unidentified micrococci in 8, *B. mycoides* in 5, monilia in 8, and saccharomyces in 8. Döderlein's bacillus was found in 10 out of 24 women in the fourth to the sixth month of pregnancy, Gram-positive cocci in 8, Gram-positive diplococci in 4, *B. mycoides* in 5, monilia in 3, and saccharomyces in 4. Döderlein's bacillus was found in 7 out of 39 women in the seventh to the ninth month of pregnancy, staphylococci in 5, unidentified Gram-positive cocci in 12, diplococci in 5, *B. mycoides* in 6, monilia in 7, and saccharomyces in 8. From the clinical point of view the women could be placed in three groups: (1) The genital organs appeared to be perfectly healthy; the predominant organisms in this group were Döderlein's bacillus, Gram-positive micrococci, streptobacilli, and *B. mycoides*. (2) There was moderate leucorrhoea without lesions of importance; in this group the commonest organisms were Döderlein's bacillus, Gram-positive cocci, *B. mycoides*, saccharomyces, and monilia. (3) There was vaginitis, often with lesions of the cervix, and abundant discharge; in this group Döderlein's bacillus was never found, the commonest organisms being diplococci, staphylococci, and *B. mycoides*. It is to be noted that Döderlein's bacillus was rather less frequent in the second group than in the first. It would appear, therefore, that this organism is commoner in the early months of pregnancy than during the later, and commoner in healthy than in diseased conditions.

388. The Reversion of Rough to Smooth Pneumococci.

H. A. REIMANN (*Journ. Exper. Med.*, February, 1929, p. 237) finds that if a smooth strain of pneumococcus is grown in broth containing its specific type antiserum rough colonies appear after a few transfers. Some of these rough colonies give off daughter colonies, which are indistinguishable morphologically from the original smooth colonies, but which nevertheless in their serological behaviour and in their absence of pathogenicity to mice are similar to the rough variants. The importance of these "colonially" smooth but antigenically rough variants is that if they were encountered in the sputum they would almost certainly be classified in Group IV. By inoculating mice with these variants, or with the real rough variants, together with killed pneumococci of Types I, II, or III, it was found that a reversion to the original smooth form sometimes occurred. Occasionally a transformation was observed into a smooth form of a type different from that from which the rough variant was originally derived.

389. Buccal Vaccination of Mice with B. typhi murium.

K. KUMAGAI and A. MOTOMURA (*C. R. Soc. de Biologie*, February 22nd, 1929, p. 493) find that, for mice of 8 to 15 grams in weight, a dose of 0.001 mg. of a culture of *B. typhi murium* is uniformly fatal when given by the mouth. Attempts were made to vaccinate mice against this organism by the buccal route, forty mice being used. The daily dose of vaccine was 4 to 5 mg. (of presumably killed bacilli), the duration of the vaccinating process was 30 to 80 days, and the total dose of vaccine given was between 120 and 400 mg. At the end of these periods the mice were tested with different doses of living organisms. Though the number inoculated with each dose is not stated, it appears that all animals which received by the mouth a dose of 0.001 mg. survived. As this dose was uniformly fatal to unprotected mice the authors conclude that it is possible to produce immunity against mouse typhoid by the oral administration of vaccine.

GLAXO LABORATORIES

GLAXO HOUSE, LONDON, N.W.1

THE scientific staff of the Glaxo Research Laboratories has amongst its duties to supervise and control the production and packing of all Glaxo, Ostelin, and Maltine lines, so that the Medical Profession may prescribe any of them, confident in the knowledge that the patient will receive an article of the highest possible efficacy and value—be it a matter of bacteriological purity, of chemical constancy, or of vitamin content.

OSTELIN PRODUCTS

"OSTELIN" IN GLYCERIN: 3 minims are equivalent in vitamin D value to one drachm of cod-liver oil. Valuable for dispensing.

"OSTELIN" TABLETS: The most suitable form for adults. In all hypotonic conditions and wasting conditions generally. Contains calcium glycerophosphate.

"OSTELIN" EMULSION: Contains "Ostelin" equivalent in vitamin D value to 50% cod-liver oil, with calcium glycerophosphate.

OSTOMALT: "Ostelin," malt extract, and orange juice; contains calcium glycerophosphate. An unrivalled means of providing vitamins A, B, C, and D.

"OSTELIN" AMPOULES: For intramuscular injection. Each ampoule contains 1 c.c. of a sterile solution of "Ostelin" in olive oil.

ELIXIR "OSTELIN": When diluted 1 to 7 is equal in vitamin D potency to the finest medicinal cod-liver oil.

"OSTELIN" with PARATHYROID TABLETS: Sugar-coated tablets, containing equivalent to 3 minims "Ostelin" in glycerin, two grains of calcium glycerophosphate, and one-fortieth grain of desiccated parathyroid.

MALTINE PRODUCTS

MALTINE (*PLAIN*): Contains the concentrated elements of wheat and oats in addition to barley, in the form of a thin syrup, with a standardised diastatic strength (1000 B.P.C.).

MALTINE WITH COD-LIVER OIL: A perfect emulsion, palatable and easy of assimilation.

MALTO-YERBINE: A stimulating expectorant invaluable in bronchial catarrhal conditions.

MALTINE with CASCARA SAGRADA: Specially valuable in post-natal conditions. Provides the gentle laxative required at this period.

MALTINE WITH CREOSOTE: Indicated in tuberculosis, and in septic conditions of the alimentary canal.

MALTINE WITH PEPSIN AND PANCREATIN: Contains three principal digestants—Diastase, Pepsin, and Pancreatin, in proportions capable of converting all foods into the soluble condition necessary for proper assimilation.

SUNSHINE GLAXO with added vitamin D

Sunshine Glaxo (in the white tin) contains OSTELIN. This added vitamin D not only enhances the value of the food for infant feeding, but also makes it a most beneficial food for expectant and nursing mothers.

FOR EXPECTANT AND NURSING MOTHERS the quantity of Sunshine Glaxo recommended is: twice daily, two tablespoonfuls to a breakfast cup, adding water just off the boil.

The new Ostelin product for use in nasal catarrh

The new "Ostelin" product, **OSNOL**, is a solution of vitamin D in liquid paraffin for use in nasal catarrh.

The clinical results have been most encouraging, even in some cases where a variety of remedies had been unsuccessful.

In the pure vasomotor type of catarrh, where there is no gross deformity of the nasal passage, the results have been uniformly excellent. Cases associated with structural abnormality, cases of recurring catarrhal deafness and of frontal headache of sinus origin, have all reported marked improvement.

OSNOL
NASAL SPRAY

OSNOL is used in an atomiser, suitable for oily solutions, and is applied to the nasal passages two or three times daily.

In 1 oz. phials - 3/-

Any request for further information should be directed to Glaxo Laboratories, London, N.W.1

Analysis:—

"the complement of Medical Diagnosis"

THE

ANALYTICAL

LABORATORY

AND

ITS FUNCTIONS

Claims of Efficient Service to the Profession are incomplete without reference to—

THE ANALYTICAL LABORATORY and its activities.

The importance of a correct analysis is fully appreciated by the busy Professional man, often supplying data which may mean some modification of the original diagnosis. The case may present baffling symptoms, the cause of which may be revealed by analysis. The infinite variety of samples handed in day by day for analysis indicate that the work of this Department is of great value.

ANALYSES of all descriptions undertaken.

CHEMICAL, MICROSCOPIC, BACTERIOLOGICAL EXAMINATIONS.

GENERAL ANALYSIS OF	...	Blood, Pus, Faeces, Sputum, Lung Tissue, Throat Swabs, etc.
TECHNICAL ANALYSIS	...	For Manufacturing Purposes. Water, for Salts, Contamination, Action of Lead Pipes, etc. Urine, for Albumen, Sugar, etc. Poisons, for Identification.
INVESTIGATIONS	... ...	Acidosis, Autogenous Vaccines.

A few examples of work undertaken—

FOODSTUFFS etc.	Milk	for T.B., Fat Content, Adulteration.
	Cream	for Rancidity, Fat Content.
	Jam	for Glucose, Sugar, Foreign Matter.
	Tobacco	for Nicotine, Dust, etc.

All investigations undertaken by a skilled staff of Chemists and results carefully checked before reports are submitted.

PUBLIC NOTICE

re

"RYVITA CRISPBREAD"

and

"THE RYVITA CRISPBREAD HABIT"

We acknowledge with much pleasure and grateful thanks the volume of congratulations on our successful introduction of "Ryvita Crispbread" to the British Isles.

When we gave to the British public this new and invaluable food—creating throughout our country the *Ryvita Crispbread habit*—we started what has now become almost a revolution in the bread-eating habit of the nation.

"Ryvita Crispbread" is the successful outcome of generations of experience directed to making just this one thing *right*.

That it is, and does, all that we claim for it is proved by the welcome it has received from Doctors, Dentists, and food experts, who not only prescribe it but have it as the daily bread in their own homes.

Because of its success, not only with the professions and the experts, but with the ordinary folk of these islands, there have arisen a number of "imitation Crispbreads." Some of these are not bad—*as imitations*—some are bad, some quite bad.

We make "Ryvita Crispbread" in Sweden because this type of bread is essentially and characteristically Swedish. The special ovens which we use are a mere item compared with the skill and long experience needed to make Ryvita *right*. It has taken generations of experience devoted exclusively to making just this type of bread to win the present perfection of "Ryvita Crispbread."

Although we make "Ryvita Crispbread" in Sweden, we who own and control the Ryvita Company are British. We buy British when it is best. But, like most other British people, we *will* have the best.

When we smoke a cigar it must be—Havana made in Cuba. After dinner, when we offer our friends a glass of port—it must be port from Portugal. When we have a little party, our champagne must be genuine from France. The suggestion that you should buy imitation Crispbreads merely because they are "British made" is as ludicrous as it would be to claim pre-eminence for British Cigars—British Port—or British Champagne.

Whilst the Ryvita Company is proud of its achievement in popularising the healthful *Ryvita Crispbread habit* in this country, it *entirely dissociates itself from these hastily* prepared substitutes.

The genuine original "Ryvita Crispbread"—crisp, scrunchy, and delicious . . . the bread of life and health—helps to make indigestion, constipation, malnutrition, and obesity unknown.

"Ryvita Crispbread" is sold by all good grocers and stores at 1/6 per 40–50 slice (1 lb.) carton; ½ lb. carton, 10d.

THE RYVITA COMPANY
413, RYVITA HOUSE
96, SOUTHWARK STREET
LONDON, S.E.1

★ FREE—*A postcard sent to-day will bring you by return a generous free sample of the genuine original "Ryvita Crispbread"*

"RYVITA CRISPBREAD MAKES YOU FIT—AND KEEPS YOU SLIM"

Approved and appreciated

by the Medical Profession

Our authority for that statement is the steadily increasing demand from all over the world.

H.M. Government departments are repeatedly purchasing Taylor's. Foreign Governments also ask for Taylor's. The reason is that Taylor's Zinc Oxide Plaster has been tested and found pre-eminent.

Only the best surgical cloth is used. The plaster mass, of the finest rubber and highest quality ingredients, is scientifically tested and analysed. Thus a perfect strapping, which grips firmly without fear of slipping, is produced.

A standard product, guaranteed free from deterioration over a number of years and absolutely unaffected by climatic conditions. Antiseptic and non-irritating. Made in five and ten yard spools, in nine widths from a quarter of an inch.

Also in rolls, seven inches and twelve inches wide.

A test is best. A free sample spool willingly sent on request to Dept. "P.," Edward Taylor Ltd., Salford, Lancs.

Salt and Son Ltd.

Natural Ambulatory Treatment

FOR

TALIPES VARUS

Note the Divided Construction

Why Salt's Patent Boot and Leg Instrument has been successful in over 2,000 cases.

It is necessary, after an operation for Talipes Varus, to have restrictive means of holding the foot in the correct position, and so to complete the success, not mar, the results of clever surgery.

The use of plaster-of-Paris prevents normal walking exercise, retards growth, and atrophies the leg.

Salt's Patent Varus Boot and Leg Instrument may be used as restrictive splintage, and so prevent the natural tendency of the foot to revert to its varus condition. The great feature of this well-known appliance is that the foot and ankle are held in normal position; the inward rotation of the limb from below the knee is prevented, and the patient is enabled to take normal walking exercise.

In over 2,000 cases we have not found any shortening of the leg AFTER the use of this appliance.

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, which delighted Medical Men at the recent B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

Stocked by all Chemists and Druggists, Boots 800 Branches, Timothy White Ltd., Taylor's Drug Stores, and Parkes' Chemists Ltd.

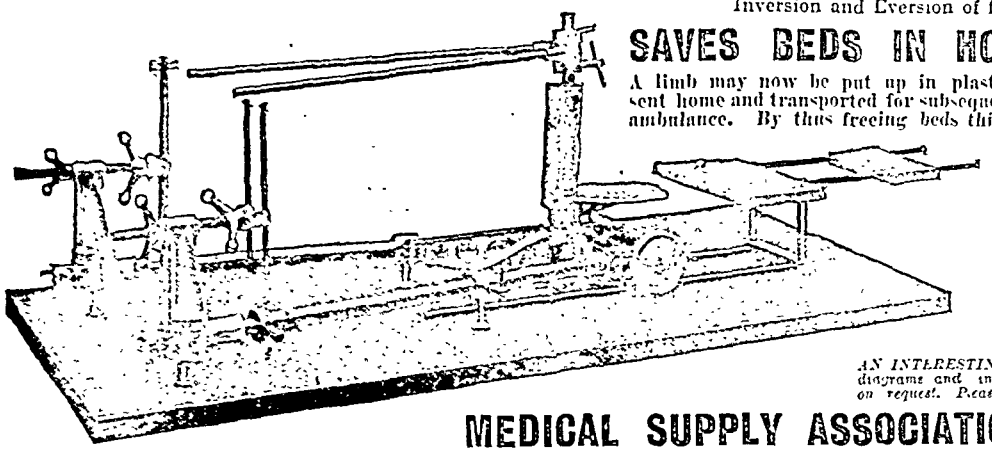
An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.



SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 32 in. × 14 in. × 7 in.

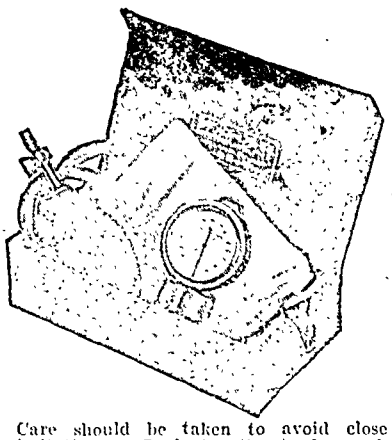
Accurate Arterial Pressure Readings

For visiting purposes the TYCOS Portable Sphygmomanometer amply fulfils the Physician's needs. Although one of the most delicate and accurate instruments of the medical man's equipment, the portable type as illustrated can be carried without fear of breakage. There is no glass tubing to break, no mercury to spill, and the readings can be verified at a glance by comparing the relation of the hand to the immovable zero.



Care should be taken to avoid close imitations. Look for the trade mark 'TYCOS' engraved on the dial of every genuine instrument.

Obtainable from all reputable Instrument Dealers.

Vapo-Cresolene Est. 1879

Sold by all Chemists

Write for descriptive Booklet No. 67B.

ASTHMA

There are certain types of chronic asthmatics who require relief of their paroxysms. While adrenaline is generally effective, it must be given hypodermically, and its action is short lived. Vapo-Cresolene (specially prepared cresols of coal tar) vaporized in the bedroom at night will give the desired relief. The patient is not disturbed as he breathes the medicated air of the bedroom.

This antiseptic vapour is particularly effective in bronchial ailments accompanied with cough and difficult breathing—as bronchitis, whooping cough, spasmodic croup.

ST. ANDREW'S HOSPITAL
FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most *modern* treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged *immersion bath, Vichy* Douche, Scotch Douche, Electrical baths, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a *Department for* Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. *On the North-West side of the Estate a mile of sea coast forms the boundary.* Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone: No 56 Northampton), who can be seen in London by appointment.

City of Liverpool.

ASSISTANT CITY BACTERIOLOGIST.

The Health Committee of the Liverpool Corporation require the services of an Assistant City Bacteriologist. The duties will be to carry out the routine bacteriological examination of milk and other food-stuffs, Wassermann Reactions, etc., and perform such other work as may be required, under the direction of the City Bacteriologist.

The salary will be £600 per annum.

Candidates, whose age must not exceed 35 years, should be registered medical practitioners having had special experience in bacteriology.

The person appointed shall devote his whole time to the post and will not be allowed to engage in private practice, and all emoluments out of public monies which may be payable to, or received by him will have to be paid to the Corporation. He will be subject to the superannuation provisions of the Liverpool Corporation Act, 1921.

Applications, stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials, endorsed "Assistant City Bacteriologist," should be sent to the undersigned not later than April 22nd.

Canvassing of members of the City Council is strictly prohibited.

HOUSE SURGEON (male) preferably with knowledge of X-ray. Salary £120 p.a., with board, residence, and laundry.

Applications, with copies of three recent testimonials, to the Honorary Medical Supt.

Willesden Urban District COUNCIL.

HEALTH DEPARTMENT.

APPOINTMENT OF DENTIST.

The Willesden Urban District Council require the services of a Dentist.

The duties attached to this post include the Dental Inspection and Treatment of School Children and the Dental Inspection and Treatment of Expectant and Nursing Mothers, and Children under 5 years of age, and such other duties as the Council or Medical Officer of Health may require to be undertaken.

The Dentists work under the administrative control of the Medical Officer of Health.

The appointment is terminable by a month's notice on either side, and is subject to the Council's Regulations concerning Officers of the Council, and to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The successful applicant will be required to pass a medical examination.

Candidates must possess a registrable qualification in Dentistry, and devote their whole time to the duties of the office.

Commencing salary £402 10s., rising by four annual increments to £517 10s., with Civil Service Bonus in addition, which Bonus fluctuates according to the rise or fall in the cost of living, revision being made every six months, namely March 1st and September 1st. At the present time the commencing salary and bonus is at the rate of £550 11s. 6d. per annum.

Travelling expenses within the district paid by the Council.

Application forms may be obtained on application by letter (enclosing stamped addressed foolscap envelope) to the Medical Officer of Health, Health Department, 54, Winchester Avenue, Kilburn, N.W.6, and should be returned to him duly filled in by applicant, together with copies of three testimonials, not later than 9 a.m. on Friday, April 26th.

All communications to be marked "Dentist."

E. A. PRATT,
Town Hall, Clerk to the
Dyne Road, Kilburn, Council.
N.W.6.
April, 1929.

Derbyshire Education Committee

ASSISTANT SCHOOL MEDICAL OFFICER.

The Derbyshire Education Committee require the services of an Assistant School Medical Officer at a salary of £600, rising by annual increments of £25 to £700 per annum.

Candidates must be skilled refractionists and must have held the post of House Surgeon in an Eye Hospital or the Eye Department of a General Hospital for a period of not less than six months. In addition to eye work, the duties will include medical inspection of school children.

The officer appointed will not be allowed to engage in private or consulting practice, but will be required to devote his whole time to the duties of the office under the direction of the School Medical Officer.

Forms of application may be obtained from the undersigned, to whom they should be returned completed, together with copies of not more than three recent testimonials, on or before April 27th, endorsed "Assistant School Medical Officer."

The appointment will be determinable by three months' notice on either side.

W. M. ASH,
New County Offices, School Medical Officer.
Derby.
April 8th, 1929.

[AMENDED ADVERTISEMENT.]

Metropolitan Borough of BETHNAL GREEN.

MEDICAL OFFICER OF HEALTH.

The Bethnal Green Borough Council invite applications from persons, preferably between the ages of 30 and 45 years, for the appointment of Medical Officer of Health at a commencing salary of £1,100 per annum, rising by annual increments of £50 on approved service to a maximum salary of £1,200 per annum, inclusive of all services of any kind whatever.

Candidates must possess the qualifications prescribed by the Public Health (London) Act, 1891, and the Sanitary Officers Order, 1926. The [appointment will be subject to the approval of the candidate to medical examination, Act, By-laws, and Standing Orders of the Council.

Applications must be on forms obtained from me, and returned so as to reach me at the Town Hall, Bethnal Green, London, E.2, by noon on Tuesday, April 23rd.

Canvassing will disqualify a candidate.

DAVID J. KEEP, Town Clerk.

Sheffield Union.

NETHER EDGE HOSPITAL.

HOUSE PHYSICIAN (Lady).

The Guardians invite applications from duly qualified ladies for the appointment of Resident House Physician at their Nether Edge Hospital. The Hospital [has] 550 patients, and [is] for 32 patien[ts] in addition, set aside for tuberculous patients.

The lady appointed will be required to act under the direction of the Medical Superintendent of the Guardians' Hospitals, and to take duty at the pre-natal clinic of the Sheffield Corporation at such times and for such periods as may be arranged or approved by the Medical Superintendent.

The appointment will be for one year, at a salary at the rate of £150 per annum, with the usual residential allowances.

Applications, stating age, professional qualifications, and experience, and accompanied by copies of not more than three recent testimonials, must be sent to the undersigned by not later than April 20th.

LAWRENCE RICHMOND,
Union Offices, Clerk to the Guardians.
West Bar,

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(FOUNDED 1880.)

12, Stratford Place, Oxford Street, W.1.

Tele. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 / 1783}

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Practices and Partnerships for Disposal. Full particulars sent free.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone*: GERRARD 3543 (5 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

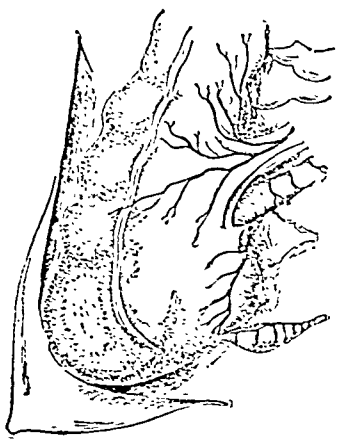
No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. SOUTH COAST.—Popular and favourite Watering-place.—Old-established increasing mixed-class PRACTICE, worth last year nearly £1,600, including panel of over 1,150, and offering further scope. Visits 3/6 upwards. Mids. from 4 gns. About 30 cases yearly. House contains eight rooms, with usual offices, and garden. Price £1,450 (at least £1,000 can be obtained on mortgage). Held by Vendor, who will give efficient introduction, over 9 years.
2. SHEFFIELD.—Better-class non-panel and non-dispensing PRACTICE, averaging approximately £3,000 p.a., and offering good scope. Suitable house can be obtained in developing district. Premium 1½ years' purchase, with 12 months' introduction.
3. PARTNERSHIP.—OUTLYING WESTERN SUBURB.—A one-third or one-half share is for disposal in a well-established mainly better working-class Practice, producing over £2,300 p.a. Appointments worth about £100 p.a., and panel of 1,400. Fees from 2/6 to 21/-. Lowest midwifery 3 gns. Purchaser (if single) could reside in rooms, or suitable house obtainable. Premium 2 years' purchase.
4. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non-panel general and surgical Practice can be acquired by a suitable gentleman possessing the F.R.C.S. degree. Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation, at present held on lease with option to purchase. Premium 2 years' purchase.
5. SOUTH-WESTERN COUNTY.—LARGE SEAPORT TOWN.—Old-established mixed-class PRACTICE averaging over £3,000 p.a., including panel of 2,100. Visits 3/6 to 10/6; midwifery (discouraged of late) 3 gns. upwards, about 30 cases yearly. Expenses light (Assistant not necessary). House contains professional accommodation, 3 sitting, 6 bedrooms, bathroom, etc. Large garden, garage. Vendor's freehold price £2,800, of which £1,200 can remain on mortgage, or might be rented at £96 p.a. Premium 1½ years' purchase, £3,000 down and balance by arrangement.
6. BUCKINGHAMSHIRE.—Country PRACTICE, situated in delightful district within 50 miles of London.—Old-established mixed general Practice, producing a steady average income of £2,000 p.a. Panel brings in about £700 p.a. Moderate expenses. Fees from 2/6 to 21/-. Under 30 midwifery cases yearly. Exceptionally nice and well-situated house, with 2 reception, 6 bedrooms, etc.; separate entrance to professional rooms. Large garden, with tennis court. Price for freehold £1,500. Hunting, golf, and other sport. Premium £3,000.
7. HOME COUNTY.—Within 40 miles of London.—In small Village (with large surrounding population) in pleasant district, old-established mixed and increasing PRACTICE, worth last year nearly £3,600, including Union and Vaccination over £100, and panel producing over £1,150. Railway station in place. House contains surgery and waiting rooms (separate entrance), 2 reception, 4 bedrooms, bathroom, etc., large garden. Gas, electric light available. Price for freehold £2,500, part mortgage. Premium 1½ years' purchase. Good society, sport, etc. Vendor keeps an Assistant, but investment would admirably admit of taking a partner later on, as houses available.
8. HERTS.—PARTNERSHIP.—A one-third share (and up to one-half in two years' time) is offered in an old-established mixed general Practice, averaging about £2,000 p.a., with good scope. Non-panel at present, but ingoing partner should undertake this work. Fees 3/6 to 7/6, a few at 15/-. Little midwifery 3 to 10 gns. Suitable house can be bought. Sport of all kinds. Premium 2 years' purchase.
9. LONDON, WEST END.—PARTNERSHIP.—A one-fourth or one-third share is for disposal in an old-established good-class non-panel, non-dispensing Practice. Net income of share £1,120. Fees one guinea upwards. Very little midwifery from 31 guineas. Suitable flat available for bachelor, or if married purchaser could choose his own place of residence. Premium for one-fourth share £2,250.
10. SOUTH OF ENGLAND.—In a pleasant town (pop. 11,000) within 5 miles of favourite watering-place, old-established mixed-class and increasing PRACTICE worth nearly £1,300 last financial year, including transferable appts. and panel of 880. Excellent family residence, standing in its own grounds (tennis court, flower garden, etc.), with ample accommodation. Held at present on lease (2½ years to run) at £90 p.a., and can eventually be bought for £1,700 or less. Premium £2,040, to include drugs, fittings, some furniture, etc.
11. PARTNERSHIP.—SOUTH OF ENGLAND.—The two-fifths share (producing an income of at least £1,300 p.a.) can be acquired by a suitable gentleman in an old-established connection situated in an attractive town near the sea. Appts. and panel held. Visits 5/- upwards, medicine extra. Very little midwifery. Nice house available, held on short lease, but can be purchased. Excellent educational facilities, and sport of all kinds. Premium 2 years' purchase.
12. SOUTH-WEST OF ENGLAND.—PARTNERSHIP.—A one-half share in a very old-established Practice situated in an attractive small town, amid beautiful surroundings, and within easy reach of the Coast. Gross cash receipts for the past year over £2,900. Panel of 1,218, which, together with appts., brings in about £900 p.a. Moderate expenses. Visits 2/6, plus mileage and medicine 2/6 and 3/6 extra. Very suitable house, with 3 reception, 4 bedrooms, and usual offices. Garden. Price for freehold £750, of which £350 on mortgage. Premium 2 years' purchase.
13. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses. Sport of all kinds and schools. Premium 2 years' purchase, part by arrangement if necessary. Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
14. CORNISH RIVIERA.—In a small but rapidly growing town (pop. 5,000—6,000) on the Coast, an old-estab. PRACTICE producing last year over £1,000, including appts. and panel of 550 to 600. Opposition weak. Delightful residence, standing in own grounds of 1½ acres (croquet and tennis lawns, etc.) and eminently suitable for Resident Patients, which Vendor has been in the habit of taking. Contains professional rooms, 4 reception, 9 bedrooms, 2 bathrooms, etc. Water and electric light. Garage. Price for freehold £4,000. Prem. £1,500.
15. LONDON, SOUTH-WEST.—Within three miles of Charing Cross.—PARTNERSHIP.—A half share, with succession to the whole in about two years, in a very old-established non-panel Practice, held by Vendor 26 years. Steady average income of £2,300. Surgery fees 2/6 and 3/6, visits mainly 5/- and 7/6. Very little midwifery. Good house, in main road, with garden. Held on lease, with nearly 15 years to run, at a rental of only £55 p.a. Premium 2 years' purchase. Very good scope for increase.
16. LANCS.—LARGE TOWN, within easy reach of Manchester and Liverpool.—Old-established PRACTICE. Average income for past 12 months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/6. Good house, with nice garden. Can be rented on lease at £65 p.a. Premium only 1½ years' purchase for prompt sale.
17. NEAR SOUTH COAST.—Old-established mixed-class PRACTICE, situated in delightful country district within easy reach of two favourite towns. Income last year over £1,600. Panel of about 700. Fees 3/6 to 21/-. Midwifery 2 to 7 gns; very few cases. Good house, standing in its own grounds, with 2 reception, 5 bedrooms, etc. Garage for two cars. Sport of all kinds, and good schools within reach. Premium £2,250.
18. PARTNERSHIP.—Within 5 miles North-West of Charing Cross.—The half share of an old-established middle and working-class Practice, averaging about £2,100 p.a., including panel of 1,300. Visits 2/6 to 10/6. House contains, in addition to professional accommodation, 2 reception, 2 bedrooms, bathroom, kitchen, etc. Small garden. Net rental, on lease, about £60 p.a. Premium 2 years' purchase.
19. KENT.—Old-established Country PRACTICE, situated in very favourite locality within 5 miles of the coast. Income for past 12 months £1,030. Surgery fees 3/6 upwards, visits 5/- to 21/-. Poor Law appt. and panel of about 380. Attractive commodious house, with separate professional rooms. Small garden. Price £1,800. Premium £1,500.
20. LONDON, NORTH.—Old-established centrally situated mixed general PRACTICE. Income for the immediate past year £3,500, including panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Long introduction.
21. KENT.—COAST TOWN.—Small, but increasing middle and working-class PRACTICE, producing for last 12 months nearly £600. Panel of 560. Visits 3/6 upwards. Not much midwifery at from £3 3s. Double-fronted eight-roomed house, with three-quarters of an acre of garden. Premium £900.
22. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients—upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.
23. SOUTH OF ENGLAND.—LARGE SEAPORT TOWN.—PARTNERSHIP.—A half share in a chiefly working-class Practice, offering large scope for increase. Income last year nearly £950, including panel of 900. Fees 2/6 to 5/-. Has been worked as "Lock-up," but suitable accommodation can be obtained. Premium 1½ years' purchase.
24. WARWICKSHIRE.—PARTNERSHIP.—A one-third share in a mixed-class Practice, producing about £3,600 p.a., including panel of about 2,500. Fees 3/-. upwards. Suitable house, with 2 reception, 4 bedrooms, etc. Garden. Garage. Can be rented at £100 p.a. Premium 2 years' purchase.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

Among the Results of Constipation



Distended and sagging cæcum compressing and obstructing blood supply of vermiform appendix.

are not only the grave toxæmias of which much has been learned in recent years, but also conditions arising from mechanical factors, due to displacement of the viscera or pressure exerted by the distended bowel.

AGAROL Brand Compound, combining three essential actions: lubrication of the intestinal tract, restoration of the peristaltic force, and softening of the impacted fæces, generally aids in overcoming the effects of constipation. Gentle but forceful in action, Agarol Brand Compound assists the organism back to regular normal evacuation by restoring *peristaltic function.*

The dependability of Agarol Brand Compound has definitely enlisted the interest of the medical profession, who in most cases of acute or chronic constipation, successfully prescribe Agarol Brand Compound — one tablespoonful on retiring.

Agarol Brand Compound is the *original* Mineral Oil—Agar-Agar Emulsion with Phenolphthalein

no griping or pain; no nausea; not habit forming.

A Liberal Quantity For Trial To Physicians

During Convalescence

'Metatone'

A NEW AND UNUSUAL RECONSTRUCTIVE TONIC

'METATONE' is unique in that it contains an active extract of vitamin B in solution with nucleinic acid and the glycerophosphates of sodium, potassium, calcium, manganese and strychnine. These are combined in a palatable, clear, wine-red vehicle.

'Metatone' may confidently be prescribed in cases of anæmia, malnutrition, convalescence from operations and debilitating diseases, and all run-down conditions generally. One to two teaspoonfuls after meals is the dose; as a stomachic tonic it is better given before meals.

Supplied in bottles of 8, 16 and 80 fl. ozs. A specimen and further particulars will be supplied on request.

INTERMEDIATE HOSPITAL IN ANNEXE AT 17, PARK LANE

Helped by an endowment fund, an Intermediate Hospital of 30 beds (later to be increased to 50 beds) is now open for suitable general surgical cases at 17, Park Lane, London, W.1. The fees for a room cost now only two guineas a week, interest in the scheme having made possible a further reduction since it was started.

(The whole scheme is an attempt to help people unable to pay ordinary full surgical expenses, and yet at the same time to avoid any semblance of a charity which would be distasteful to such.)

All further particulars can be obtained from the Secretary or Matron at 17, Park Lane.
Telephones: Grosvenor 2312 & 2313.

A TYPICAL SCALE OF REDUCED FEES FOR SURGICAL CASES IN THE ANNEXE CLINIC OF THE HAROLD FINK MEMORIAL HOSPITAL AT 17, PARK LANE.

Hospital Fees, including Nursing, 2 guineas a week (limited to an average stay of 3 weeks)	£6	6	0
Dressings, Theatre Fees, etc.	1	1	0
Assistant Surgeon at operation	4	4	0
Anæsthetic Fee	4	4	0
Surgical Fees for Major Operation (from one-fifth usual charges, according to patient's means) ... ... (say)	21	0	0
(From Thirty-five guineas inclusive fee)	£36	15	0

N.B.—The patient must be recommended as a suitable case for these reduced fees by their own Medical Attendant, who will take charge of the after-treatment while in hospital, and be paid direct by the patient his usual fees for such attendance in addition to the fee as Anæsthetist or Assistant at operation.

When the patient's doctor wishes to arrange a preliminary consultation with the Surgeon-in-Chief (with a view, for example, to a Bismuth Meal, Cystoscopic or X-ray Examination, etc.), all that is necessary is to telephone either the Secretary or Matron, and an appointment will be made. (Proportionately reduced nominal fees only charged therefor.)

Telephones: Grosvenor 2312 & 2313.

All rooms are of course separate, and hold one patient only, there being no wards.

FELAMINE

BRAND SANDOZ

An association of the most powerful cholagogue—pure crystallised cholic acid—and the classical biliary disinfectant—hexamine, entirely free from accessory substances.

Indications:

CHOLANGITIS, CHOLECYSTITIS, HEPATIC INSUFFICIENCY, HEPATIC CONGESTION, JAUNDICE, CHRONIC CONSTIPATION.

Felamine is supplied in Bottles of 50 and 250 Tablets.

London: 40, Gloucester Place, Portman Square, W.1

SECOND EDITION. NOW READY.

MOVABLE KIDNEY Its Etiology, Pathology, Diagnosis, Symptoms, and Treatment

By WILLIAM BILLINGTON, M.S.Lond., Ch.M.Birm., F.R.C.S.Eng.

For the second edition, the Author has largely rewritten this book in the light of wider experience. After having operated upon upwards of 1,500 patients, he claims that his results prove that in carefully selected cases great benefit, and even absolute cure, can be obtained from his method of nephropexy. In the closing chapter he quotes a report by Professor Kauffmann upon his last series of cases confirming this claim.

Several new plates have been introduced, including two pyelograms.

Demy 8vo, 192 pages. With 14 Plates and 8 Figures in the Text. 12s. 6d. net.

CASSELL & COMPANY, LTD., La Belle Sauvage, London, E.C.4.

"MEDISUN"

ULTRA-VIOLET LIGHT APPARATUS

100% BRITISH.

Specification :

The "MEDISUN" Ultra-Violet Light Apparatus is of the quartz mercury vapour type. It has been so designed as to eliminate all unnecessary expense, and yet provide an efficient source of ultra-violet radiation, quick in its reaction speed, not requiring adjustment, and foolproof in its mechanical details. Whilst the price of the "Medisun" is quite low, its appearance is really first class. Manufactured in polished aluminium throughout, it does not require frequent cleaning, is designed to stand on any table, weighs only 14 lb., and is a thoroughly reliable piece of apparatus.

RUNNING COST: 30 TREATMENTS 3d.

Price:
For use on Direct Current ... £12
For use on Alternating Current £18

THIRTY OTHER TYPES

IMPORTANT NOTICE

RADIOGRAPHY at the PATIENT'S BEDSIDE

or

LOCAL COTTAGE HOSPITAL

We have pleasure in announcing to the medical profession that to meet the increasing demand for facilities for X-ray Examination and Radiography in non-ambulatory cases, where no X-ray plant or radiologist is available, a special travelling service has been arranged for this purpose.

Specially fitted Cars, with their own Generating Plant and X-ray Equipment, are available and can be sent with a trained Radiographer to any part of Great Britain.

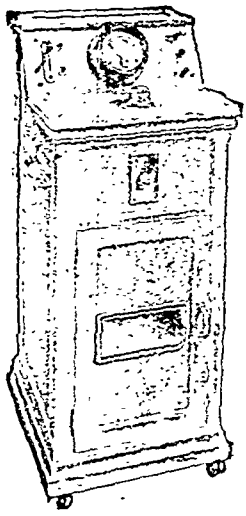
One or more Radiographs are taken, developed, and presented to the Medical Adviser before leaving.

The special attention of the medical staffs of Cottage Hospitals having no X-ray equipment is drawn to this service, as it will be an undoubted boon to them in assisting diagnosis and to the patients in the relief of suffering. Should sufficient support be forthcoming a regular service could be instituted at a moderate cost.

NOTE: *Please write for full particulars of this unique service, which is restricted to members of the medical profession and hospitals, and will only be carried out at their request.*

THE COX-CAVENDISH ELECTRICAL CO. (1924) LTD.

LANGHAM 105, Great Portland Street, London, W.1. [1145



The outfit is of neat and handsome appearance, the wooden cabinet is finished in white enamel, all metal parts are nickel plated, and the control panel is of marble.

THE POWER OF "VITA" GLASS IS PERMANENT

It allows Constant Passage to the Ultra-violet Rays year in and year out

The power of "Vita" Glass to transmit the ultra-violet rays is stabilised permanently within a few months after it is fitted. Thereafter it may be accepted as a perpetual inlet for the health rays in daylight.

This fact (and ample proof of it is readily available), will serve to reassure medical practitioners who may have hesitated to recommend "Vita" Glass for the windows of their patients.

Now that an average-sized bay window in a modern house can be "Vita" Glazed for 38/- plus the cost of fixing, it has become quite a practicable course for private persons even of quite moderate means.

Further information about "Vita" Glass with the names of some of the 180 hospitals and 100 schools with "Vita" Glass windows will be forwarded to any interested medical man. Write to the "VITA" GLASS MARKETING BOARD, 9, Aldwych House, London, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

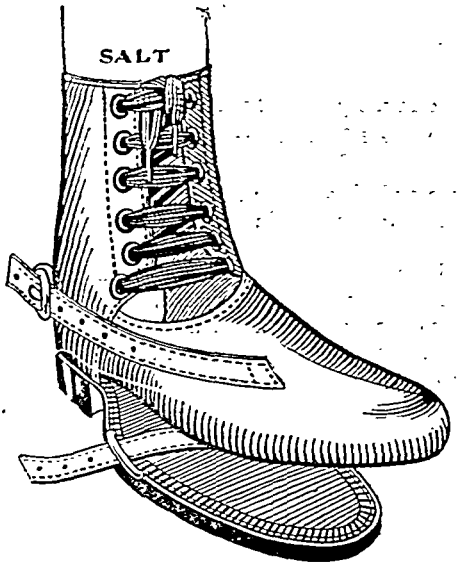
Salt and Son Ltd.

SALT'S PATENT VARUS BOOT

WITH LEG INSTRUMENT

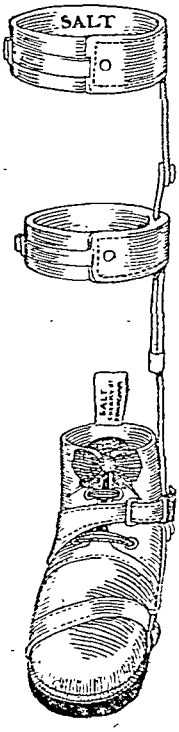


Note the Divided Construction

In most cases of Talipes Varus the ankle goes over outwardly, the patient walking on the outer border of the foot. Also, there is a tendency for the limb, from knee downwards, to rotate inwardly.

It is of extreme importance that these features should be corrected in the early stages, such correction being achieved as follows:—

1. The back of the foot can be held firmly by the boot; the loose front portion holding the toes everts the front portion of the foot by strap traction.
2. The "T" strap pulls the ankle-joint comfortably and easily into correct position when fastened over the leg instrument.
3. Finally, the leg instrument, when carried above the knee-joint, prevents the internal rotation of the leg from below the knee.



Thus the foot and leg are held in normal position, allowing the child perfect freedom in walking.

Where extra lightness is required (as in the case of a young child) the instrument can be made in duralumin, which has the advantage of being half the weight of steel.

BELLE VUE SPA

TREFRIW, NORTH WALES

(Railway Station Llanrwst and Trefriw)

Telephone—LLANRWST 60. Telegraphic Address—"BELLEVUE, TREFRIW."

AMBULATORY TREATMENT LTD.

THE establishment is at Trefriw village and occupies a sheltered fold of the western slopes of the Conway Valley, about 15 miles from Llandudno and 5 from Bettws-y-Coed. Its terraces and windows command the pleasant contours of the river and the hills.

Although on the fringe of the central mountain mass of Wales, its rainfall is no greater than that of London, and its climate is far milder. It is protected from all the colder winds; in winter there is rarely any frost or snow. Here, the facilities of an up-to-date nursing home have been combined with the comfort and cuisine of a charming country hotel, and a complete equipment has been assembled for the treatment of affections of the bones and joints by progressive modern methods.

The Spa is remarkable, amongst all other Spas both at home and abroad, for the strength and purity of its iron springs. The geological conditions are peculiar. The waters percolate from a mountain tarn a thousand feet above, and pass through deposits of pyrites embedded in the hills which shelter Belle Vue on the west. By taking advantage of ancient tunnellings left by a forgotten generation of miners, and only recently brought to light, it has been possible to tap the iron waters at their source, a considerable depth below the surface of the mountain side. They issue from the pyrite beds in a state of complete purity, the iron salts being entirely in that ferrous form appreciated by the physician and the pharmacist. They are secured before there has been any opportunity for oxidation to occur from exposure to the air, and oxidation is still further retarded by the presence of minute amounts of Sulphurous Oxide. For these reasons there is no contamination by admixture with even traces of ferric salts whose irritant and astringent properties are undesirable in waters intended for internal use.

The Chalybeate spring provides a ferrous water which is not only absolute in its purity, but unique in its concentration. It contains more than 3 per cent. of anhydrous ferrous sulphate. The equivalent of a Blaud's pill is to be found in less than one ounce. It affords a means of applying a natural iron therapy in which the dose of iron can be closely regulated. The patient need not imbibe a large volume of water in addition unless it should seem desirable for him to do so.

The method is proving invaluable in the secondary anæmias of rheumatic conditions; also in chlorosis, chronic septic anæmia, the anæmias which follow acute infection, and those resistant forms peculiar to protracted illness and chronic disease.

The Iron Springs at Trefriw are much stronger than any other pure ferrous waters in the British Isles. They are, in fact, twenty times as strong as the next in series. Abroad the strongest pure ferrous waters are at Ronneby, in Sweden; but these are only one-fifth as strong as those of Belle Vue Spa.

Many medical men have written about the curative properties of these ferrous waters in the early cases of arthritic origin, so-called rheumatism.

From my own observation I find that patients treated by my manipulative extension method derive great benefit, not only from drinking the waters as an addition to the extension cure, but also by the beautiful air, and last, but not least, the incentive to improve the blood supply by walking amongst the beautiful country surrounding Trefriw.

Also C. A. HOEFFTCKE, 7, Harley Street, London, W.1.

Telephone—LANGHAM 1510.

COLLECTING OVERDUE ACCOUNTS "WITHOUT OFFENCE"

Often debtors do not pay because of the way they are approached for a settlement. A bullying manner, or too curt a letter, will not only make a Client seek new Professional attendance—he will also forbear paying as long as possible.

Below is a copy of a letter from a debtor whom one of our Members originally tried to collect from in the wrong way.

Dear Sir,

As regards the enclosed, I should have paid long ago had it not been for what I consider the very unprofessional procedure meted out to me.

I now enclose my cheque.

Yours faithfully,

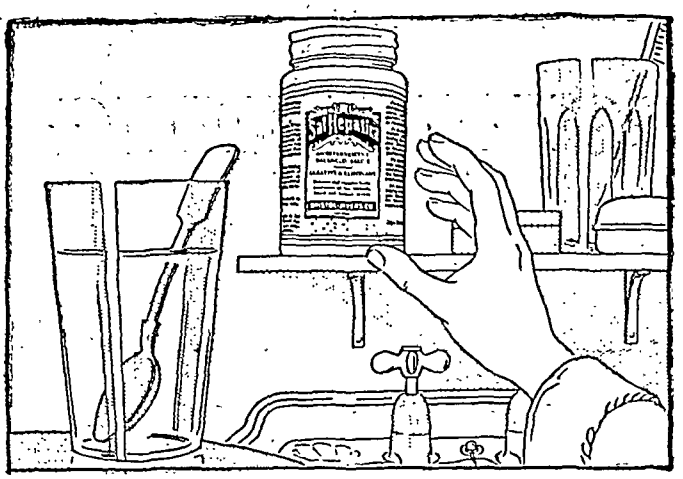
KEROL CAPSULES



In all cases of auto-intoxication

Diabetes, rheumatism, gout, sciatica, lumbago, neuritis and many other similar diseases have been found to have their origin in auto-intoxication, which gives rise to acidosis. ¶ The speedy and thorough evacuations induced by Sal Hepatica expel all auto-intoxicants from the system, while the blood and urine is rendered alkaline. ¶ Sal Hepatica stimulates the biliary flow, thereby relieving hepatic congestion, and restores the daily habit of defecation by natural means. It is non-habit-forming, non-irritant and entirely painless in its action. Sal Hepatica is only advertised to the medical profession.

Sal Hepatica

the proved medicinal saline laxative and cholagogue.

¶ Sal Hepatica contains sodium sulphate, sodium phosphate, sodium chloride and lithia citrate in an effervescent medium.

Samples for clinical trial will be forwarded on request to duly qualified members of the medical profession on application to

BRISTOL-MYERS COMPANY, 112, Cheapside, London, E.C.2

NOVOCAIN

The Original Preparation
English Trade Mark No. 276477 (1905).

Local Anæsthesia in Surgical Practice

CANCER OF THE GREATER CURVATURE OF THE STOMACH.

Typical Case.

Operation: Gastric Resection.

D E aged 60 years.

Technique of Anæsthesia: Local infiltration and anterior splanchnic. A transverse infiltration across both recti was made, using 150 c.c. of a 0.5 per cent. Novocain-Adrenaline solution. The abdomen was opened with perfect negative pressure, and a large tumour in the great curvature presented in the incision. The lesser omentum was infiltrated with Novocain-Adrenaline solution and divided. After a thorough examination of the liver, which revealed no signs of metastasis, it was decided that the case was probably operable. The retroperitoneal space, which was exposed after dividing the gastro-hepatic omentum, was carefully infiltrated with Novocain-Adrenaline solution. The duodenum was then divided between clamps beyond Hartmann's lines. This manœuvre was also painless. The jejunum was anastomosed to the lower portion of the gastric incision, the remainder of which was closed with linen. The patient's pulse was 74 at the completion of the operation, with no change in his colour or general condition except that he was tired. The operation required one hour and thirty minutes. His recovery was uneventful.

—Extract from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Absorbs Intestinal Toxins

Over thirty-six separate poisons have been found in the intestinal tract in cases of alimentary toxemia. These consist of bile acids and alkaline wastes secreted by the intestinal mucous membrane, in addition to a variety of bacterial ptomaines and toxins.

Nujol is a highly active solvent. If it be shaken with a watery solution of indol, more than half the indol is quickly taken up. Nujol readily dissolves these waste and poisonous substances, many of which are more soluble in liquid petrolatum than in water.

Thus Nujol, which is not absorbable, takes up a very considerable portion of toxins found present in the intestinal tract and prevents their absorption into the body. The brownish colour of Nujol as seen in the stool is due to the substances which it holds in solution.

Laxatives which liquefy the intestinal contents and provoke anti-peristalsis, frequently increase the absorption of intestinal toxins. Nujol not only dissolves and removes intestinal toxins, some of which are highly active poisons even in minute quantities, but also by speeding up the intestinal rate of flow it prevents their formation. Effective in all types of constipation.

Liquid Paraffin

For the Rational Treatment of Constipation and Stasis by Lubrication.

"Chrismol"

The Ideal Lubricant

Unirritating and universally applicable.
Does not interfere with digestion or absorption.
Effectively overcomes mechanical friction from hardened fæces.
Does not cause griping or gaseous distension.
Continued use does not produce "habit," lead to chronic gastro-intestinal catarrh or lose its effect as purgatives are liable to do.

Perfectly pure and innocuous.

Conforms to higher standards than those of the B.P.

Viscosity determined at body-temperature to produce maximum lubricating effect.

Tasteless, colourless, odourless.

Descriptive literature and a clinical trial sample will be sent post free to members of the medical profession.

Allen & Hanburys Ltd. BETHNAL GREEN, LONDON, :: E.2.

OVALTINE

BEFORE AND AFTER OPERATION

As a diet preparatory to surgical operation "Ovaltine" possesses unique advantages. It tends to keep the metabolism of the patient as nearly normal as possible. It also avoids a long period of starvation prior to operation, consequent irritation of the stomach by the gastric flow, and predisposition to greater irritation from the anæsthetic.

"Ovaltine" provides a means of nourishing the patient three or four hours before operation. It is almost completely absorbed, and therefore the stomach and intestines are empty at the time the operation is conducted.

"Ovaltine" lessens the predisposition to shock and counteracts the tendency to acidosis common after chloroform and ether anæsthetics.

In the usual processes of post-operative feeding by easy stages, from sips of water to the regular diet, "Ovaltine," by reason of its delightful palatability, ready digestibility, and high nourishing power, is ideally adapted.

A liberal supply for clinical trial sent free on request.

has enjoyed the confidence of the medical profession for over 90 years. A nourishing stimulant that demands the least amount of energy in the process of assimilation and increases the means of defence by raising the powers of resistance.

Mark it in your memo book

Brand's Essences are scientifically prepared, in jelly form, from the finest English meats, and contain upwards of eleven per cent. of proteid. The nourishing and stimulating properties are IMMEDIATELY ABSORBED, without residue, in the alimentary canal. No time is lost in process of assimilation. No work entailed by the digestive organs. Absolutely pure. Contains no gelatine, colouring, or preservatives. Good for young and old alike.

BRAND'S ESSENCE OF CHICKEN contains the same nourishing and stimulating properties as Brand's Essence of Beef, and for over 90 years has been recommended by the medical profession when required by prevailing conditions.

Sold by Chemists Everywhere.

'PANOPEPTON'

Lean Beef—the entire group of nitrogenous substances, those natively soluble and those rendered soluble by physiological hydrolysis, amino-acids, and polypeptids, with the natural savoury extractives and minerals:

Entire Wheat Grain—the peculiar complex of nitrogenous substances, those naturally soluble and those rendered soluble by physiological hydrolysis, amino-acids, and polypeptids, the farinaceous substance converted into dextrin and maltose, and with the associated savoury constituents and minerals.

Of the beef nothing is excluded but the indigestible connective tissue and lipoid. Of the wheat nothing is excluded but the insoluble inert cellulose and silica of the shell of the grain.

'Panopepton' is of a uniform standardized composition; it is highly agreeable; requires no preparation. It is a potent restorative and emergency food in serious straits; a fortunate recourse for the invalid.

Supplied in 12-oz. bottles.

Originated and Manufactured by
Fairchild Bros. & Foster (Inc. N.Y.),
NEW YORK, and 65, Holborn Viaduct, LONDON, E.C.1

Agents:
Burroughs, Wellcome & Co.,

For Head Colds Prescribe "Mistol"

MISTOL and the Mistol Dropper are a real advance in nose and throat therapy. Menthol, eucalyptol, and camphor are combined in a specially prepared petroleum base, which keeps these soothing and healing ingredients in direct contact with the mucous membrane for a considerable length of time.

Unlike douches, Mistol avoids any possibility of sinus trouble. With head tilted back, the patient should let Mistol drop into each nostril until it is felt to be running into the back of the throat. It is manifestly superior to salves which do not reach all parts of the mucous membrane.

Especially efficacious in coughs and colds, simple, congestive, and catarrhal rhinitis, hoarseness, bronchitis, and laryngitis.

Sold in original sealed cartons containing a—

Mistol
(Registered Trade Mark)

Two-ounce Bottle and Mistol Dropper.

CONTRAMINE

The value of Contramine in cases of gonorrhoea with chronic complications has led to the recognition of this drug as one of the best means available for combating all types of chronic gonococcal infection.

Contramine is also of remarkable value in cases of rheumatism, arthritis and fibrositis even when not of gonococcal origin.

Literature and clinical reports on request

Contramine is supplied in ampoules which contain the drug in sterile, aqueous, isotonic solution ready for intramuscular injection; it is issued also in pessaries for the treatment of gonorrhoea in women.

Specially indicated in
NEPHRITIS - URÆMIA - ECLAMPSIA - ALBUMINURIA
and allied conditions.

PROMPT and proper diagnosis of kidney conditions is necessary in cases of Bright's disease and all types of renal disorders. In nine cases out of ten the administration of a specific capable of producing real results in compensating for the loss of kidney function is also necessary.

For more than a quarter of a century Nephritin has been a sheet anchor to physicians in treating such disorders. Nephritin Tablets induce a marked increase in nitrogenous waste elimination. They reactivate the cells of the kidney, increase urinary secretion, and induce a greater output of urea.

Given in sufficient dosage these tablets produce marked results, and restoration to normal is quickly stimulated. They are invaluable also as a prophylactic in renal complications of infectious diseases and during pregnancy. The tablets are composed of the hormones of the normal kidney as they appear in nature—absolutely unaltered.

The confidence of the MEDICAL PROFESSION.

Benger's Food has gained its unique position not by extravagant or sensational advertising but by the constant recommendation of medical men and women. To-day it is universally used not only at home but throughout the world. Few foods have so enjoyed the approbation of the Medical Profession for over 40 years.

Benger's Food differs from all other foods in that it is especially prepared to adjust fresh cows' milk or cows' milk and water so as to suit the condition of any patient. While it is largely used as a routine treatment in all cases of disordered digestion the following comments, which have been recently made by Doctors, indicate some specific uses to which Benger's Food has been put.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."

"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."

"cancer of the stomach—doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."

"invariably used for invalids and aged persons."

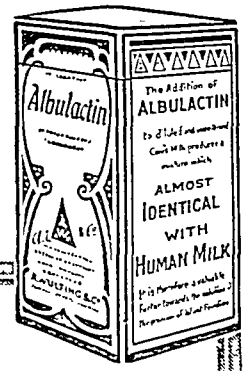
Wulfing Products



The Pale and Weakly Child . . .

Particularly the type in which a definite pathology cannot be demonstrated, generally responds well to calcium therapy in the form of Kalzana. For instance, a recent clinical report states:

> *"I gave Kalzana to a child with peculiar symptoms of apathy, listlessness, etc. There has been a marked improvement—she sleeps better, and takes her food with some appetite."*

The clinical results produced by Kalzana are equally satisfactory in diseases of children amenable to calcium medication, especially in tubercular disease, and the type of malnutrition associated with acute infectious disorders.

Kalzana is a definite chemical combination of calcium-lactate and sodium-lactate in the form of a double salt. The special virtue of the product is due to the action of the sodium in raising the blood alkalinity to the extent necessary to secure the adequate retention of the calcium constituent. Therefore Kalzana therapy means calcium retention. It is used in over 200 British Hospitals and Sanatoria, including many leading Children's Hospitals.

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

Kalzana

THE LIME FOOD

Precision in Infant Feeding

Every requirement needed to provide a correctly balanced infant's food is supplied by properly modified cow's milk and Albulactin. The all-important proteid and lactalbumin percentages are exactly correct, and *always* within the control of the physician; an important consideration when the food has to be adapted to the peculiar digestive capacities of individual infants.

Albulactin is pure lactalbumin—the vital proteid of human milk—supplied in the form of an impalpable powder. It is quite simple to prepare, and may be prescribed with confidence in all cases of artificial feeding, from the premature weakling to the normal healthy infant.

The British Medical Journal says:

> *"There appears to be every reason to expect this preparation to prove of great value in the 'hand feeding' of infants."*

Supplied in bottles at 1/9, 3/6 and 7/-

Albulactin

Made by A. WULFING & CO., Amsterdam, Holland.

Supplies for your own dispensing, and for Hospitals, Sanatoria, etc., are available on special terms. Adequate samples for clinical trial sent with pleasure upon request.

Diet in debility

IT has been demonstrated that many cases of illness which manifests itself mainly as debility, associated with headache, constipation, nervousness, and in severe cases recurrent (cyclical) vomiting, are due to Ketosis. This is a condition which is primarily due to disturbance of the function of the liver as a consequence of which digestion and assimilation of fat are markedly retarded or even for the time abolished. If, however, sugar is added to the diet the disease is rapidly cured.

It is evident that when fat is administered to children it should not be in a form that gives rise to derangement of the function of the liver and heart muscle, and that it should be guarded by an adequate quantity of sugar.

In the treatment of debility, apart from a sufficiency of protein, carbohydrates, and fats, a sufficiency of mineral salts, notably calcium and iron, and a well balanced vitamin content are of great importance.

These conditions are admirably fulfilled in Virol, which is composed of Marrow Fat, Glycerine Extract of Red Bone Marrow, Malt Extract, Eggs, Lemon Syrup, with Salts of Lime, Iron, etc., and which has been shown by independent investigations to contain all the vitamins.

The great value of Virol in debility and wasting conditions has been proved in a widespread clinical experience and by its continued use in more than 3,000 Hospitals and Clinics.

COTTAGES DEPICTED IN ANCIENT INDIAN SCULPTURES. The cottage, of which the front is here shown, is entered by double doors, the room on either side being lighted by a window. At the left is seen the gable end of a second dwelling, having two windows, one in the gable and a second beneath it. The houses are apparently built of sun-baked clay. Three or four similar cottages, belonging to different members of the same family, appear to have been built round a quadrangle. In the scene, a woman stands in the quadrangle holding a basket into which a measure of grain is being poured by a merchant whose assistant stands outside with two baskets slung on a pole. The earliest Indian houses were built of wood, and many were still so constructed at the time of the sculptured scenes here reproduced. All later Indian architecture is derived from these early buildings, a study of which is necessary if we are to understand subsequent architectural manifestations. In the complex forms of decoration of the stone-built palaces of a later period we see constantly repeated certain structural details of the first dwellings of wood, bamboo and thatch. The "Horse-shoe" window, for example, was derived from the bent bamboo of thatched roofs of the type illustrated in the gable end of the cottage on the left. Three-storied houses or palaces also are depicted in the same sculptures, but 70 to 80 per cent. of the inhabitants of early India dwelt in cottages.

Bowel Infection and the DERMATOSES

It has long been recognized by dermatologists that absorption of bacterial products from the intestines is the key to many skin troubles. In other words, a large number of dermatoses are symptomatic of bowel-infection due to alimentary toxæmia. In the treatment of all such symptomatic maladies of the skin, a new era has been opened up by the discovery of the benzene derivative Dimol.

With the introduction of Dimol, the *bactericidal equivalent* of 140 grains of pure phenol can be administered four or five times a day without affecting the mucosa or producing any toxic effect whatever. Dimol is a powerful bactericide—thirty-five times more efficient than pure phenol; it destroys the causal agents of infection and putrefaction—*it does not merely inhibit their growth.* Dimol is not absorbed; after doing its work it is voided with the faeces.

Excellent results have been reported from the use of Dimol on psoriasis, acne, urticaria, purpura, infantile eczema and other skin disorders. The dermatologist who wishes to push his investigations into the fascinating subject of the relation of the alimentary toxæmias to skin troubles is now furnished with a powerful weapon of research. It is of importance that all medical men should realise that intestinal disinfection is now an accomplished fact.

After long and thorough investigation, Dimol pulverettes are now supplied by the Admiralty for use in His Majesty's Ships and Royal Naval Hospitals.

Some Points ON THE ETIOLOGY, PROGNOSIS, AND TREATMENT OF GRAVES'S DISEASE.*

WITH PARTICULAR REFERENCE TO THE ADRENAL GLANDS AND THE VALUE OF READ'S FORMULA.

BY

F. S. LANGMEAD, M.D., F.R.C.P.,

PROFESSOR OF MEDICINE, LONDON UNIVERSITY; DIRECTOR OF MEDICAL UNIT, ST. MARY'S HOSPITAL.

IT is not my intention to attempt to deal fully with the several aspects of Graves's disease, but rather to touch on certain points in etiology, prognosis, and treatment which in my opinion are worthy of some consideration.

The subject is one of which our knowledge is steadily growing, and about which there is much variation in opinion and practice. This is as it should be, for there is plenty of scope for trial and observation in many directions in this disorder at the present time, but little excuse for dogmatic assertions or rule-of-thumb procedures.

ETIOLOGY.

A tenet which has materially delayed advance in our understanding of Graves's disease is that hyperthyroidism is a sufficient explanation. The conception is a simple one, and suggests a simple remedy. If the symptoms and effects are due to hyperthyroidism, let us cripple the thyroid in some way or other, and necessarily the symptoms must abate. Such a simple conception, entrenched as it is in the textbooks by the use of Graves's disease and hyperthyroidism as synonymous terms, we know now is untenable, and must be modified in various ways. The discovery and preparation of a product of thyroid activity—thyro-iodin or thyroxin—led to its being regarded as the peccant substance to excess of which the symptoms are due, but Williamson and Pearse[1] have shown that disturbance of the iodo-colloid function has only an indirect relation to the thyro-toxicosis. These workers have demonstrated that the thyroid gland has two distinct functional activities—one the production of thyro-iodin, the other of a secretion—and that it is this latter which is directly related to the thyro-toxicosis of Graves's disease. Even so, the question we must answer before we can approach the preventive medicine of Graves's disease or remain satisfied with its present treatment is: "Why is the secretory activity enhanced?" When the correct answer to that question is provided the present methods of treatment, directed towards *destroying the activity of the gland by local means*, will be a subject chiefly of historical interest. I do not wish to attempt to belittle the present-day value of such methods, but I feel that it should be our aim to minimize the need for their employment, which will assuredly be attained when we can explain the overproduction of thyroid secretion. This part of the field of etiology is, then, well worthy of exploration, and one likely to yield results of the greatest practical value.

Stimulation of Thyroid Activity.

It is generally agreed now that the thyroid reacts to toxic factors, as well as to sympathetic stimulation, by increasing its functional activity. Another stimulus arises from the sex glands in the female, probably from the uterus, for there is slight but noticeable enlargement of the gland at puberty, during pregnancy, and even during menstruation in many subjects; whilst with the termination of the climacteric the opposite is prone to occur, the gland shrinking and perhaps becoming so insufficient as to permit of the development of myxoedema. Perhaps this extra duty of the thyroid in the female may explain the greater incidence of Graves's disease in women, especially during the child-bearing period.

Despite the careful work of McCarrison and others, the conception of the thyroid as an antitoxic gland was long in gaining credence, though it seems now to be acknowledged. I believe this activity to be of great importance in the etiology of Graves's disease. Like others, I have been especially impressed with the frequency of tonsillar sepsis in my experience. This has led me to make particular inquiry and investigation into the point in my last 50 cases of Graves's disease. In 22, or 44 per cent., I obtained a definite spontaneous history of severe recurrent sore throats or quinsies. In 8 of these (16 per cent.) an attack occurred while the patients were in the wards. It must be emphasized that simple sore throats were disregarded in these figures, and only severe and recurrent tonsillitis or quinsies were considered.

Stimulation of the thyroid gland by toxins, either acting alone or in combination with other exciting influences, seems to me to be among the most important causes of thyro-toxicosis or Graves's disease. It is tempting to suppose that the effect of local sepsis, such as that of the tonsils, is to create a demand for the iodo-colloid secretion, but that by this demand the whole gland is stimulated, the true secretion being also increased. It is this excess of true secretion which provides the symptoms of Graves's disease. Bearing upon these points it must not, however, be forgotten that hyperplasia of the secretory tissue of the thyroid seems to hold in check the development of iodo-colloid, for removal of some of the hyperplastic tissue is followed by a re-accumulation of iodo-colloid in the alveolar spaces (Williamson and Pearse).

The Adrenals in Graves's Disease.

The part played by the adrenal glands in Graves's disease cannot be ignored, but is not easy to assess. Psychical causes, such as worry, excitement, mental stress, and fright, have long been recognized as precursors. Moreover, the clinical picture of the disease is the very presentment of fear—the starting eyes, the flushing, the tachycardia, the tremor, even the diarrhoea and the hyperglycaemia, together delineate the features of fear. But fear and the preparation for fight or flight we believe to be intimately connected with activity of the adrenal gland, the hormone of the medulla of which hurries up the heart, braces up the blood vessels, and mobilizes sugar for immediate effort (Cannon). When Graves's disease begins abruptly, following a period of excitement and alarm such as a motor accident, it is difficult to exclude the adrenals in its production, for the increase of adrenaline which arises, by stimulating the sympathetic system, must provoke also increased thyroid secretion. During the war one saw many examples of men who, after exposure to danger, presented a picture which during time of peace one had been accustomed to recognize as mild Graves's disease, for they showed tremor, tachycardia, flushing, slight staring of the eyes, with retraction of the upper lids and visible sclerotics below them. In most instances these symptoms subsided quite quickly, being gone in a few hours or days, but occasionally true Graves's disease followed and persisted. There was, I believe, a notable increase in Graves's disease in London during the war period, which has been ascribed to the air raids (Langdon-Brown). If we accept the modern physiological explanation of the reaction to fear, the prominent part played by the suprarenals in the inception of Graves's disease in these cases can hardly be denied.

A more difficult question is as to how long this adrenal activity persists, and how far it contributes to the picture of the developed disease, for it must not be forgotten that administration of thyroid alone in excessive doses is capable of producing nearly all the symptoms. Yet it is reasonable to infer that with overaction of the thyroid there is accompanying overaction of the adrenals, for thyroid secretion stimulates the sympathetic, which in turn stimulates the adrenals. Assuming that my contention is right that suprarenal activity precedes that of the thyroid in response to psychical disturbances in certain cases of Graves's disease, it is easy to see how a vicious circle may be set up. The outpouring of adrenaline stimulates the sympathetic, which in turn stimulates the thyroid and the suprarenal itself, whilst the increased thyroid secretion for its part stimulates the adrenals still more.

[3563]

*Read before the Hampstead Division of the British Medical Association, March 14th.

Experimental Study of the Suprarenal Gland.

There are several interesting observations and experiments which bear upon this problem. W. Cramer[2] points out that the suprarenal gland is unusual in that its own secretion stimulates it to further activity through the intermediation of the sympathetic, a process which, unchecked, would inevitably lead to exhaustion of the gland. He finds that injection of adrenaline or of whole adrenals in a mouse produces characteristic changes in the adrenal medulla, which he believes effect a control of the gland. The changes in the gland are an apparent hyperplasia of the deeper part of the cortex, at the expense of the medulla. *Hedinger and Herring*[4] found enlargement of the suprarenal cortex as the result of prolonged feeding with thyroid. Possibly, as Cramer suggests, an explanation of Graves's disease is to be found in a breakdown of this controlling mechanism.

The experiments of Marine and Baumann[5] are especially suggestive. After suprarenalectomy, or after freezing the adrenal cortex with ethyl chloride in rabbits, they found that 38 per cent. (of 31 rabbits) showed markedly increased heat production (which corresponds to a raised basal metabolic rate) for months, loss of weight, and "a picture resembling the exophthalmos-complex of exophthalmic goitre." These results did not occur if the thyroid gland was previously removed—an observation strongly indicating a controlling action of the suprarenal cortex against thyroid secretion and activity in Graves's disease.

McCarrison has shown that inanition provokes hypertrophy of the suprarenal cortex. May not this hypertrophy be a protective mechanism to control metabolic activity by opposing the thyroid? Jaffe[6] has shown that suprarenalectomy causes rapid enlargement of the thymus, and we know that thymic hyperplasia is a constant accompaniment of Graves's disease. Marine states that thyroidectomy hastens involution of the thymus, whilst suprarenalectomy delays it.

Shapiro[7] has given a glycerin extract of ox suprarenal cortex in cases of Graves's disease, and records considerable benefit, especially upon the asthenia, dysmenorrhoea, diarrhoea, nutrition, heat production, tachycardia, and blood pressure. He believes that the suprarenal cortex exerts an inhibitory or regulating control over the thyroid, and that its functional insufficiency plays a fundamental part in the development of Graves's disease. He points out that suprarenal cortical injury and Graves's disease have many features in common, for both show increased metabolism and sometimes thyroid hyperplasia, lymphoid hypertrophy, including that of the thymus, asthenia, increased sexual activity, hypersensitiveness to toxins and drugs, and increased pigmentation. Marine's work on the high metabolic rate after excision of the suprarenals is not entirely confirmed by Swift,[8] and Bornstein and Holm,[9] who found a diminished ventilation of the lungs, to which they attribute it.

Lucas, Obregia[10] has treated Graves's disease with glycerin extract of whole suprarenal glands of sheep, pigs, calves. He records rapid amelioration of the condition, and states that all the patients have recovered. With adrenaline given by the mouth he obtained improvement, but this was less pronounced than with the whole gland.

A clinical feature of interest in regard to the suprarenal cortex being a possible factor in Graves's disease is the pigmentation. In Addison's disease the pigmentation is generally regarded as due to cortical rather than to medullary defect, and a somewhat similar pigmentation is common in Graves's disease. Feeding of birds with thyroid, on the other hand, causes disappearance of pigment.

To sum up the etiological part of my remarks there is, I think, good reason to believe that:

1. Hyperthyroidism is an incomplete definition of Graves's disease.
2. An important provoking antecedent is local sepsis, especially of the tonsils.
3. The suprarenal glands play an important part in the etiology and clinical manifestations.
4. There is a good deal of evidence to show that suprarenal cortex exerts a controlling influence on thyroid secretion, and that its failure to control is an important factor.

PROGNOSIS.

Estimation of the severity of a case and a forecast of its probable outcome is based best on the assessment of many factors, and should not, in my opinion, depend entirely on the basal metabolic rate. The degree of tachycardia, the pulse pressure, the cardiac rhythm, the severity of nervous symptoms, the degree of general weakness, the existence or not of diarrhoea are all factors of great importance. The age of the patient is another pertinent consideration, for with the intervention of the menopause amelioration is to be expected. Occupying a prominent, perhaps the most prominent, position is the value of the basal metabolic rate, but it should be taken in conjunction with other features, and should not be used as a direct index of severity as though it possessed mathematical accuracy. The plan of deciding upon the treatment, whether operative or non-operative, by the reading of the basal metabolic rate alone is one which is less often adhered to than formerly, for it is recognized that slight variations in the records alter the final estimation exceedingly, that errors in technique are easily committed, that slight psychical disturbances profoundly modify the result, and considerable fluctuation may occur within a comparatively short period. If, however, we can disabuse our minds from regarding the rate of basal metabolism as an unfailing signal owning mathematical exactness, it remains an index of great value. A serious drawback to its use is the difficulty of estimation, considerable practice being needed to obtain accurate and comparable readings; indeed, the necessary apparatus has found its way into the armoury of few practitioners in this country. Some simple formula would be valuable if it approached the basal metabolic rate estimation in the degree of its accuracy.

Read's Formula.

A formula introduced by Read is not difficult to work with. It is as follows:

$$\tfrac{3}{4}(\text{P.R.} + \tfrac{3}{4}\,\text{P.P.}) - 72$$

where P.R. is the pulse rate, and P.P. the pulse pressure. Taking a normal patient with, say, a pulse rate of 72 and the pulse pressure of 40 the sum is thus:

$$\tfrac{3}{4}(72 + 30) - 72, \text{ which is equal to } +3.$$

To test the degree to which Read's formula approximates to the basal metabolic rate Dr. T. C. Hunt, recently of the St. Mary's Hospital Medical Unit, has compared the two in a limited number of cases: 54 were examined in all, but of these 4 were rejected, the basal metabolic rate being regarded as unreliable in view of excitement, nervousness, or other cause. Of the remaining 50, in 27, or 54 per cent., the two agreed within 10; in other words, they gave results which for practical purposes may be considered as equal. In only 3, or 6 per cent., did Read's formula give a result higher than the basal metabolic rate by over 10. (This agreed with the opinion of Eason, who states that Read's formula agrees with the basal metabolic rate in 50 per cent. of cases.) In 6, or 12 per cent., Read's figure was between 10 and 20 less than the basal metabolic rate; in 8, or 16 per cent., between 20 and 30 less; and in 6, or 12 per cent., it was more than 30 less. These last 6 were all cases with high basal metabolic rates, the average value being + 73.

Dr. Hunt draws the following conclusions:

1. Read's formula will very seldom give appreciably too high an estimate of the basal metabolic rate, but often gives slightly lower figures.
2. A very marked discrepancy suggests an error in technique.
3. The basal metabolic rate in very bad cases is probably fairly considerably higher than Read's formula suggests.
4. Iodine treatment appears to improve the circulatory system as shown by Read's formula more definitely and more permanently than it improves the basal metabolic rate, which does not appear to be reduced for long by the comparatively small doses given (up to 20 minims of Lugol's solution daily). With this exception Read's formula has shown improvement with treatment exactly parallel with that shown by the basal metabolic rate.
5. Read's formula should be applied under basal conditions, but does not seem to vary so much as the basal metabolic rate from food or other external factors. In some cases it is quite impossible to gauge the latter accurately.

Within limits it would seem that the figure obtained by this formula is an accurate guide to progress, and differs widely from the basal metabolic rate figure only in the severest cases. It has a particular field of usefulness when for some reason estimation of the basal metabolic rate is not practicable.

TREATMENT.

The psychical and toxic factors in the causation of Graves's disease suggest at once two lines of treatment. The value of rest and freedom from mental excitement is too well known to need emphasis here. Removal of a focus of sepsis is also clearly indicated if the importance of such in the etiology be conceded. Unfortunately these two lines of treatment are in part antagonistic, for such an operation as tonsillectomy, for example, in an adult who has had repeated quinsies is no light one, and cannot be undertaken in a case of severe Graves's disease without anxiety. It finds its chief place in early cases, or those in which the thyro-toxicosis is slight. The question of focal sepsis should be borne in mind whenever an early case is encountered, or at a stage when the full clinical picture is still lacking. Its detection and consideration at this stage may be of great value as a preventive measure.

The modern treatment by administration of iodine, especially in the form of the French tincture or of Lugol's solution, has largely replaced earlier drug treatment. There can be no doubt of its potency, for within a very short time definite improvement is obvious in many cases, whilst the thyroid gland can be felt to become firmer. Unfortunately there is less certainty about the permanence of the good effect. Most English, German, and American observers hold that prolonged treatment is unsuccessful. Many French authorities, however, are of the contrary opinion. Thus Dautrebande,[11] Labbé,[12] and Boudreau[13] state that iodine must be administered over many months, with gradually increasing dosage up to 0.5 or 0.6 gram of metallic iodine, given five or six times daily. These are truly heroic doses compared with the 2 to 10 minims of Lugol's solution, three times daily, customarily employed in this country. The rationale of iodine treatment is ambiguous, and, indeed, iodine would appear definitely to be contra-indicated if it were true that Graves's disease is hyperthyroidism, and that its toxicosis is caused by excess of thyroxin. The recognition, however, that the thyro-toxicosis is related to excess of other secretion, and not to that of the iodo-colloid substance, suggests another explanation. May it not be that administration of iodine relieves or assists the thyroid in its reaction to toxins, and thus indirectly, by lessening its functional activity, reduces the output of the secretion which causes the thyro-toxicosis? In view of the unsatisfactory experience of others I have treated only a few patients by persistent and prolonged iodine therapy. The chief results have been gain in weight and lessened excitability and tremor, but there has been little beneficial effect upon the basal metabolic rate or the cardio-vascular symptoms. It must be confessed, however, that I have not yet had the temerity to use the large doses so forcibly recommended by some French writers.

About symptomatic treatment I shall not particularize as I have little new to advance. There are many occasions for such measures during the course of the disease. A mixture containing digitalis and bromide is, of course, one which has been very generally employed to combat the tachycardia and fibrillation, and to procure sleep and reduce the mental excitement. My belief is that digitalis should be used only with great caution in Graves's disease, for in this condition it may do serious harm.

There remain to be considered the two destructive procedures, which are used to cripple the over-activity of the thyroid gland—namely, *x*-ray therapy and operative procedures. There is no doubt that both may produce great amelioration of the symptoms, and may hasten recovery, though I think that in neither is one justified in using the word "cure." In a disease in which, under medical treatment, the tendency of the majority is slow progress in the direction of recovery, it is difficult to compute the precise value of surgical treatment unless its effects are immediately or rapidly curative. Nor is it easy to find any agreed statement as to which cases are considered by surgeons particularly suitable for surgical treatment. There are many who regard all cases as suitable, except during an acute phase; there are others who are disinclined to operate at all. It must be acknowledged, however, that the tendency in recent years has been more and more towards operation, and the operative mortality has fallen in expert hands to a very low figure. On the other hand, *x*-ray treatment has become somewhat less favoured since it has been recognized that its effects cannot be controlled with precision, and that it interferes seriously with subsequent operative procedures. The common practice of preceding operation by a course of treatment by physical and mental rest, and by the administration of iodine, has certainly lessened the danger of surgical intervention. At my hospital we have no enthusiasts for surgical treatment, and it is seldom employed on my patients. In mild cases it seems to me to be unnecessary, and in very severe cases too dangerous, while of the intervening cases improvement by medical treatment is what one is accustomed to expect. In patients near the menopause, also, relief before long is to be anticipated. Perhaps I am influenced by the belief that surgical treatment for this disease is only treatment of a secondary condition, and that our chief hope lies in being able to discover and treat the primary causes. In the meantime, surgical treatment, though it may represent only a temporary phase, has undoubtedly a sphere of usefulness. To employ it as a routine measure is, I believe, irrational, but when medical treatment fails or falters it shortens the period of invalidism, which is so serious a consideration in many patients that it more than counterbalances the added risk.

THE IMPORTANCE OF POST-NATAL MATERNAL CARE.

COMPRISING A REVIEW OF THE ORGANIZATION AND WORK OF THE POST-NATAL CLINIC OF THE EDINBURGH ROYAL MATERNITY HOSPITAL.*

BY

DOUGLAS MILLER, M.D., F.R.C.S.ED.,

PHYSICIAN TO THE ROYAL MATERNITY HOSPITAL, EDINBURGH: ASSISTANT GYNAECOLOGIST, ROYAL INFIRMARY, EDINBURGH.

It is the common experience of those whose work is concerned with the treatment of diseases peculiar to women that parturition is ultimately responsible for a considerable proportion of the disability with which they have to deal. The importance of childbirth in this regard is reflected in the large number of gynaecological patients who refer their complaint to a previous pregnancy or labour. It is an obvious corollary that the degree of skill and care with which the process of childbirth is conducted is an important factor in a woman's subsequent well-being. The prophylaxis of future invalidism, however, requires from the accoucheur not only that pregnancy and labour be so managed as to reduce to a minimum the incidence of trauma and infection, but also such careful supervision of the patient's convalescence as will best assist the processes of involution and repair and restore a maximum degree of bodily efficiency.

Whereas the claims of the expectant mother have of recent years attracted, and rightly so, a full measure of consideration, the need for a similar attitude of guidance and

* An address delivered to the Ayrshire Branch of the British Medical Association, February 27th, 1929.

watchful care during the weeks which follow delivery has scarcely received from obstetric teachers and writers the emphasis it deserves. It is with the object of directing attention to this important aspect of our obstetric responsibilities that I have chosen post-natal care as the subject of this address.

After the crisis of labour, with its major issues of life and death, has been successfully passed, the weeks which follow are apt to constitute a period of anti-climax in which watchfulness naturally tends to relax, to the extent occasionally that the patient is finally dismissed with or without a single examination after the conventional fortnight has elapsed. It is to be remembered that a minimum *period of six weeks* must always pass before the return of the pelvic organs to their normal condition is accomplished and recovery can be considered complete. Moreover, examination in a large series of women six to eight weeks after confinement has shown that even after a normal delivery, and in spite of negative examination findings at the conclusion of the lying-in period, various pathological *processes* may develop later, as the result of which recovery is short of perfect. It would appear desirable, accordingly, to extend the supervision of our puerperal patients so as to cover the period during which the development of such late complications remains a possibility.

The management of the more immediate convalescence after confinement has become so standardized that it is only necessary in passing to re-emphasize certain important principles. These comprise essentially the maintenance of asepsis, the establishment of lactation, and insistence on an adequate period of rest in bed, with simple bed exercises and frequent change of posture so as to relieve congestement of pelvic veins and ensure adequate drainage. For those who can afford it massage is beneficial, both in virtue of its general stimulating effect, and also in making good the loss of muscular tone produced by the forced inactivity of the latter weeks of pregnancy and the lying-in period.

As a routine a vaginal examination should be made about a fortnight after delivery. At this time the condition of the perineum, cervix, uterus, and appendages is investigated. Injuries are inspected and the state of healing noted. If the uterus is found to be *retroverted it* is a simple matter to replace it at this time; in such a case the patient is instructed to report in a week for re-examination. If the displacement has recurred it is again corrected and a pessary introduced, otherwise a period of three weeks is allowed to elapse before a further examination is made.

When the patient is discharged she is given general advice in regard to the immediate future of her infant and herself, in addition, she is instructed in *simple graded* exercises devised to restore tone to the overstretched muscles of the abdomen and pelvic floor. Abdominal exercises of the Muller type, combined with the use of a properly fitting corset, have been found to be of much value in preventing or arresting the development of visceroptosis to which the feeble over-stretched condition of the abdominal musculature predisposes during the weeks which follow delivery. Exercises to strengthen the muscles of the perineum and pelvic floor are similarly useful in cases in which the musculo-fascial tissues round the vaginal entrance have been over-stretched at the time of delivery.

Even when the patient's condition a fortnight after delivery is satisfactory it is a wise *precaution to encourage* her to submit to re-examination at a *later date*. Two years ago, in the Edinburgh Royal Maternity Hospital, a weekly post-natal clinic was organized for the purpose of supervising the patient's progress after she left hospital, guiding and advising during the difficult weeks of convalescence, treating in their earliest stages such sequelae of parturition as might manifest themselves after the conclusion of the lying-in period, and, in short, *ensuring that* the patient's return to health should be as *uninterrupted* and complete as possible. Every patient is instructed to attend the post-natal clinic on at least two occasions before she leaves hospital. The first revisit is made, as a rule, within two weeks, and the second about ten or twelve days after delivery. In certain cases, however, more frequent or more prolonged attendance at the post-natal clinic may be advised.

During the past two years rather more than 2,000 patients have reported for re-examination. This represents about 60 per cent. of the total number of in-patients treated by the hospital during the same period of time. Various factors have combined to prevent the "follow-up" being more complete. About 15 per cent. of the patients lived too far from hospital to permit of subsequent attendance; nearly 10 per cent. were unmarried and disappeared at once after leaving hospital; the remaining 15 per cent. could not be persuaded that the probable benefit of further examination and advice would amply repay the little inconvenience occasioned.

An analysis of these cases shows that in approximately 1,400, or 70 per cent. of the total number, the patient's general health was satisfactory, and on examination it was found that parturition had not in any way impaired the efficiency of the pelvic organs. To this number should probably be added the majority of those patients who failed to report. In the remaining 30 per cent. abnormalities of different types and degrees of importance were present. It is a measure of the importance of post-natal work that in almost one case in three special advice or treatment was called for.

RETROVERSION.

Probably the commonest, as it was one of the most important, of the abnormal conditions encountered was backward displacement of the uterus. This lesion was met with in 18 per cent. of the patients who reported to the post-natal clinic. It is noteworthy in this connexion that at the time of discharge from hospital the uterus was found to be retroverted in not more than 8 per cent. of cases, a finding which would indicate that this displacement is most likely to occur during the third or fourth weeks after delivery rather than during the lying-in period. There was in addition a small number of cases in which at the first revisit to hospital the uterus was found to be in a normal position, but in which at a subsequent examination backward displacement was found to have occurred.

An investigation into the factors which might predispose to puerperal retroversion showed that subinvolution was present in a large proportion of the cases examined, and was probably the most important individual cause of the condition. While this is so, it is probably also true that retroversion of itself exerts an adverse influence on involution, for in most cases correction of the displacement was quickly followed by diminution in the size of the uterus and disappearance of persistent red vaginal discharge. Neither multiparity nor difficult labour appeared of itself *to be of etiological importance* unless at the same time there was impairment and relaxation of the lower uterine supports, with consequent descent of the uterus; the association of retroversion and partial prolapse of the uterus was not uncommon. Early rising and hard work too soon after confinement probably operate in the same way, and explain the greater frequency of retroversion in the hospital class of patient. An important and unexpected observation in this connexion was that in cases delivered by Caesarean section the incidence of retroversion, in spite of a longer period of recumbency, was relatively much lower than in those delivered per vaginam. It was found, finally, that where retroversion had been known to exist before or during pregnancy there was a pronounced tendency for the displacement to recur after delivery.

The symptoms which puerperal retroversion may produce are difficult to define. Low sacral backache, general pelvic discomfort, and prolonged lochia rubra were present in most cases. But the condition is so often associated with other pelvic abnormalities, the result of injury or infection, that it is not easy to differentiate the symptoms produced by the retro-displacement itself from those to which other accompanying conditions may give rise. The persistence of red vaginal discharge, however, was noted so frequently in this group of cases as to be almost pathognomonic of retroversion in the late puerperium. It is probably true that such bleeding is often in large part due to an associated subinvolution, but the frequency with which it subsides so soon as the position of the uterus is

corrected and without other treatment would suggest that a mechanical factor incidental to retroversion is also involved.

Reference has already been made to the treatment of puerperal retroversion when it is discovered at the conclusion of the lying-in period. Similarly, when the displacement is first noted six weeks after delivery an attempt is made to correct it and retain the uterus in normal position by means of a Hodge pessary. As a rule the uterus can be brought forward without difficulty, although in a few cases a general anaesthetic is needed. After an interval of six weeks the pessary is withdrawn and the patient asked to attend for re-examination in a further three weeks' time. If the uterus is found to have remained in good position the patient is discharged, but advised to report should pelvic symptoms of any kind appear. If, however, the displacement has recurred pessary treatment is continued for six months.

In the majority of the cases observed the end-results of pessary treatment were in a high degree satisfactory. In a small number deficiency of the pelvic floor, tenderness in the vaginal vault, or fixation of the uterus made pessary treatment unsuitable, and in a few cases the uterus tended to retrovert as soon as the pessary was withdrawn. But in rather more than 80 per cent. of the cases which were followed up symptoms were relieved and the uterus remained in good position after the support had been removed. The earlier the displacement was discovered the easier did its correction prove to be and the less its liability to recur. On the other hand, the symptoms to which retroversion in its early stages gives rise are often so slight and indefinite that unless a routine examination is made six or eight weeks after confinement the condition must frequently remain undiagnosed until such time as its cure by non-operative methods becomes unlikely.

LACERATION OF THE CERVIX.

Laceration of the cervix, associated as a rule with eversion of the edges of the tear and localized surface infection, was found in a relatively large number of cases.* In primiparous patients, apart from the superficial fissuring which is the inevitable legacy of every first labour, injury to the cervix was found in approximately 15 per cent. of the cases examined.

As a cause of trauma of this nature difficult instrumental delivery predominates, and the most serious variety of cervical injury was found in the "failed forceps" type of case, in which failure to deliver had been due to incomplete cervical dilatation. Short of this, the lesion was found in almost every case in which complete dilatation and effacement of the cervix had not occurred spontaneously: it was present, for example, in cases in which, because of maternal or foetal distress, forceps had been applied while as yet a thin rim of cervix could still be felt. Similarly, where an attempt had been made to complete the dilatation of the cervix manually or by drawing the head down into it by forceps, laceration was the common result. On the other hand it is noteworthy that in cases in which delivery had been spontaneous, cervical injury was found in 8 per cent. of cases. In a small number of these labour had been precipitate; in a considerable proportion, however, the membranes had ruptured prematurely, and it is probable that the consequent long dry first stage of labour with dilatation of the cervix by the hard head in place of the soft bag of waters was responsible. In other cases it is possible that a constitutional friability of the cervical tissues may have predisposed to injury. The lesion was not appreciably more common in elderly patients nor did undue size of the child appear of itself to be a factor of importance.

With the immediate dangers of cervical laceration—haemorrhage and acute inflammatory invasion of the pelvic cellular tissue—this paper is not concerned. On the other hand, the eversion and subsequent infection of exposed cervical mucosa, which is so apt to interfere with healing, especially in the transverse or deep stellate type of laceration, constitutes an important puerperal lesion. It is possible at this stage to observe the early development of a condition which later may cause more or less serious ill health. Furthermore, the association of subinvolution and recent cervicitis was so frequently noted as to suggest that the process of involution may be adversely influenced by a focal infection of this type.

The immediate repair of laceration of the cervix at the time of delivery has obvious advantages. On the other hand, the increased risk of sepsis involved unless a perfect aseptic technique is assured makes the procedure inadvisable in ordinary domestic conditions. While this is so, much can be done in the later puerperium to prevent or diminish subsequent disability by controlling the tendency to eversion and by the eradication of infection before the deeper tissues of the cervix become involved.

In the series of cases under review douching, tamponage, and local applications of different types have been employed. The actual cautery, the use of which does not necessitate a general anaesthetic, has proved an effective therapeutic agent not only in suppressing infection but also in reducing eversion by reason of the cicatrization which it produces. Short of this the application once weekly of a 10 per cent. solution of silver nitrate has produced satisfactory results. In a few cases of extensive injury a plastic repair with excision of infected tissue was recommended.

SUBINVOLUTION.

Subinvolution was found with considerable frequency in the series of cases under review. In approximately 12 per cent. of those who reported to the post-natal clinic there was persistence of lochia rubra as late as the sixth or eighth week after delivery, and on examination evidence of defective involution was found. In a considerable proportion labour had been difficult and instrumental, and the adverse influence which puerperal infection, not necessarily of a major type, commonly exerts on involution of the uterus was evidenced by the frequency with which the earlier convalescence of many cases in this group had been complicated in this way. Attention has also been directed to the etiological relationship to subinvolution which retroversion and cervical infection appear to possess. The persistence of lochia rubra until the third or fourth week after confinement appeared occasionally to result from such interference with the pelvic circulation as severe constipation may produce, suitable purgation being quickly followed by cessation of haemorrhagic discharge. Only in a small number of cases could the condition be attributed to retention of fragments of placenta or membranes.

The importance of normal lactation in promoting involution was demonstrated in a convincing manner by the findings in a comparative series of two hundred cases, one hundred of whom nursed their children and one hundred did not. The duration of the red lochial discharge in the former ceased on the average on the ninth day post partum, whereas in the latter it continued until the eighteenth day after delivery.

The treatment of subinvolution was directed in the first place to the correction of such accompanying conditions as retroversion, cervicitis, constipation, or retained products of conception. Where the condition was associated with a residual pelvic infection a course of douching and vaginal tamponage was commonly employed. The administration of quinine and of ergot in some form proved a useful adjuvant in stimulating involution and in controlling persistent vaginal bleeding, although in a few cases this was so obstinate as to require curettage.

BACKACHE.

Backache proved to be a much less common disability during the weeks which follow confinement than one had anticipated. Although every patient was directly questioned in regard to it, not more than 8 per cent. of those who attended the post-natal clinic complained of discomfort of this type. Where uterine displacement, cervicitis, or other pelvic abnormality appeared to be responsible the pain was almost invariably referred to the sacral region. It was, however, only in a relatively small number

* Multiparous patients have been omitted from this analysis as the possibility of the cervix having been injured in a previous labour could not be excluded.

of cases that backache could be related to a visceral lesion. For the most part puerperal backache is of the lumbar or lumbo-sacral or sacro-iliac variety, and would appear more often to be an orthopaedic disability than an indication of gynaecological disturbance. In the majority of cases discomfort had been present for several weeks before delivery, and its origin is probably to be found in the exaggerated lordosis incident to the latter period of gestation; after the patient begins to go about the complaint may be further aggravated by faulty posture and by weakness and general relaxation of the abdominal parietes. There is considerable risk of this condition developing into a troublesome chronic disability, and from the outset treatment should be directed towards the correction of faulty posture, instruction in appropriate exercises, and the employment of a suitable brace or corset.

Apart from such relatively commonplace obstetric sequelae as those which have been considered there is an important group of cases which necessarily demands a prolonged period of supervision and treatment after delivery; such, in particular, as those in which pregnancy has been complicated by hydatidiform mole, heart disease, venereal disease, or albuminuric toxaemia. In post-eclamptic and albuminuric patients, for example, persistence of high blood pressure and albuminuria were found in more than 30 per cent. of cases, and necessitated special advice in regard to diet and in other directions.

Finally, there have been many cases in which debility, anaemia, constipation, dysuria, difficulties in regard to lactation, and other similar conditions, have called for simple advice and treatment.

There are essentially two considerations on which a plea may be based for a closer and more prolonged follow-up study of our obstetrical cases than is usually thought necessary. In the first place, the instructional value of routine examination some six or eight weeks after delivery is difficult to exaggerate. In retrospect such an investigation throws light and guidance on the conduct of labour, and, indeed, on the whole process of childbirth. It discloses the manner in which the general bodily functions have withstood or been impaired by pregnancy and parturition, and illustrates the effect on the reproductive organs which different types of labour, normal or abnormal, may exert.

Of more immediate practical value, however, than the "audit" of our work which the post-natal clinic provides *is the scope which it offers in an important field of preventive medicine.* It directs attention to certain conditions in their early stages which otherwise may remain untreated until such permanent structural changes have occurred that cure by non-operative measures becomes unlikely. In its relationship to the patient's future well-being it is complementary to, and rivals in importance, the more routine supervision and examination before delivery. No department of practical medicine would appear to provide a better opportunity of recognizing the early signs of disease and of treating them with such gratifying results.

The extent to which such a scheme of obstetrical after-care as I have outlined can be applied in general practice conditions is not easy to define. There are certain obvious difficulties, such as that of adding to duties for which remuneration is already seriously insufficient, and more, perhaps, the natural diffidence of patients to submit to what they may consider unnecessary examination. Furthermore, the incidence of post-partum morbidity is naturally lower in domestic than in institutional practice, which is so largely concerned with abnormal midwifery, and it may be claimed that the need for prolonged supervision after delivery is correspondingly less urgent in the former than in the latter. It is unfortunately true, however, that such conditions as retroversion, cervicitis, and backache may develop despite the most conscientious supervision during pregnancy and the most careful conduct of labour, and, in view of the impaired health to which such sequelae of childbirth may later give rise, a policy of after-care, even if it is restricted to the investigation and treatment of persistent vaginal bleeding, leucorrhoea, and backache, must necessarily help us to discharge more effectively and more completely the responsibilities we are privileged to exercise.

VARIATIONS IN THE INCIDENCE OF PNEUMOCOCCAL INFECTION IN THE NASAL ACCESSORY SINUSES OF CHILDREN.

BY

E. WATSON-WILLIAMS, *M.C.*, CH.M., F.R.C.S.ED.,

SURGEON IN CHARGE, EAR, NOSE, AND THROAT DEPARTMENT, BRISTOL ROYAL INFIRMARY.

PNEUMOCOCCAL infections in children began to attract my attention last summer, when I remarked that an unusually large number of the nasal accessory sinuses I examined were reported thus infected. I have turned up all such cases in my private file since the end of 1919, and found record of 1,002 patients, of whom 242 were under 15 years of age. In 52 adults a subsequent re-examination was made, so that for the present purpose there are 1,054 "cases," comprising 3,011 sinus explorations.

The technique employed throughout was that evolved twenty years ago by my father, Dr. P. Watson-Williams. Briefly, a cannula is introduced into the sinus, a small volume of sterile water is syringed in, withdrawn, and examined microscopically and bacteriologically. The sinuses generally examined were the maxillary antra and the sphenoidal; less commonly the posterior ethmoidal cells. The antrum is approached not from below through the inferior meatus, but from above through the middle, a method of great value in dealing with small children. It is comparatively rarely necessary to examine the posterior sinuses of children, especially young children. Six of the patients were under 3 years of age; the age distribution of the whole series was as follows:

TABLE I.

Age.	Patients.	Antra	Sphenoids.	Ethmoids.	Sinuses.
Years. 0–1 ...	21	41	—	—	41
5–9 ...	67	129	4	1	134
10–14 ...	154	286	41	5	332
Children ...	242	456	45	6	507
Adults ...	812	1,557	815	132	2,504
	1,054	2,013	860	138	3,011

Arranging this material in years, and expressing the incidence of pneumococcal infection as a percentage (whether of children or of sinuses examined), it was at once clear that my impression had been correct—that is, that during 1928 a very considerable rise had occurred in the rate. Further, a period of similar high incidence had passed unnoticed in 1923–24, with a much lower rate of infection before and after it. Ignoring 1922, the recorded observations for which year are too few for inference, and grouping together other years in which the incidence was closely similar, the rise and fall is seen to be from 0 to over 10 per cent., as shown in Table II.

There has been no conscious difference in technique, nor in the selection of cases for examination, to explain these variations. In order to test whether accident affected the rather small numbers involved, a similar analysis was made of the figures for "all cases," the results of which are given above. Allowing for the difference in the average number of examinations per child patient (2.1) and per adult (3.3), children form for each year so small a part of the whole that the figures for "all cases" are practically those for adults. It is seen that the incidence of pneumococcal infection for all cases shows a variation—less, it is true, *in its absolute but as great in its relative extent*, and occurring in approximately the same periods as for children. We may deduce that some definite factor operates to cause this variation, though whether this is climatic, epidemiological, or otherwise I am not competent to suggest. The incidence, however, of this infection is not solely of rhinological interest. *A priori* it might be supposed that an individual who harboured living pneumococci

in his sinuses ran a definite risk of developing a more serious form of the infection. In actual fact, 7 of the 83 patients (2 children, 5 adults) have had proved pneumococcal or lobar pneumonia, and there are possibly more, as the significance of the association has hitherto not been

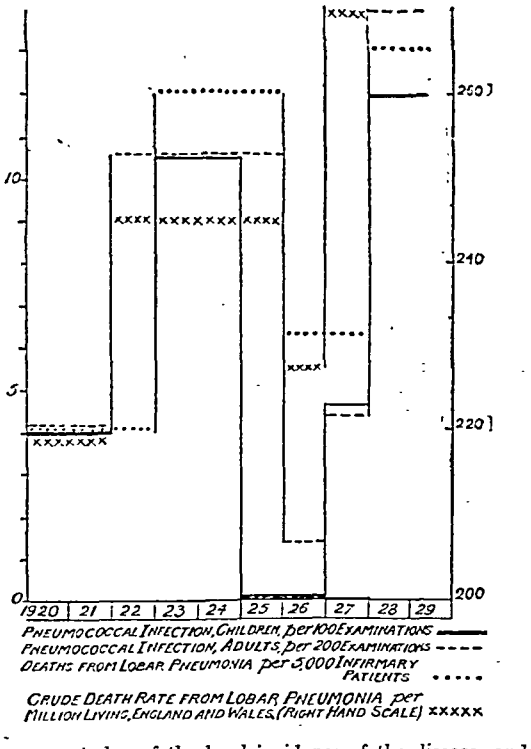
appreciated nor have special inquiries been directed to the point, two cases of pneumococcal meningitis and one of pneumococcal mastoid disease also are recorded.

By the kindness of Dr. A. D. Fraser I have been able to obtain the figures for lobar pneumonia from the *post-mortem* indexes of the Bristol Royal Infirmary. Treating



these as an index of the local incidence of the disease, and the Registrar-General's returns as a national index, we see that there has recently been a close association between the incidence of pneumococcal infection of the sinuses and that of pneumonia. All four sets of figures show a low value for 1920–21, a high value for 1923–24, a low value for 1926, and a subsequent rise. We appear now to be in a period of high incidence of pneumococcal infection; certainly the local figures for lobar pneumonia are high, and I feel tempted to predict that 1928 and 1929 will eventually show high national incidence. At least with local figures, the rise and fall of sinus pneumococcal infection tends to precede that of pneumonia; and it will be interesting to observe in the future whether variation in the nasal sinus infections (and particularly in children, in whom it seems to be greater and to appear rather earlier than in adults) forms a reliable guide to forecast the trend of mortality from lobar pneumonia. The accompanying graph illustrates the association recorded in the last ten years.

CONFUSIONAL INSANITY WITH EMPYEMA OF THE SPHENOIDAL SINUS.

BY

F. A. PICKWORTH, M.B., B.S.,

DIRECTOR, JOINT BOARD OF RESEARCH FOR MENTAL DISEASES, CITY AND UNIVERSITY OF BIRMINGHAM.

(*With Special Plate.*)

THE association of a sphenoidal sinusitis with definite macroscopic change and microbic invasion of the pituitary gland in a case of insanity is described below, and is illustrated by sketches and photomicrographs; its importance to psychiatry is emphasized by a consideration of pituitary-hypothalamic metabolic disorders in 69 cases of insanity in which a sphenoidal sinusitis had been demonstrated clinically.

A man, aged 51, died four months after admission to hospital. His early history was indefinite, but there was concussion at the age of 26. The first onset of mental disorder occurred when he was 31; from this he recovered, but relapsed again ten years later. He was suffering from confusional insanity, was talkative, disorientated, and maniacal. He had auditory hallucinations, bilateral otitis media, bilateral ptosis, and his blood pressure was 210. The Wassermann and Widal reactions were negative. Three days before death he developed epileptiform fits, after sixty-eight of which he died in status epilepticus.

Post-mortem Examination (seventy-five minutes after death; the tissues as removed were immediately placed in fresh Kaiserling solution).—There were slight superficial haemorrhages in the pia arachnoid, the largest being over the left fronto-parietal area. The cerebro-spinal fluid was slightly blood-stained in the posterior cisterns only. The dural surface of the base of the skull was clear and shiny. There was pus in the pharynx, which could be traced to the left sphenoidal ostium. The sphenoidal sinus was literally full of yellowish pus, the cavity being a large one and almost surrounding the pituitary gland. The pituitary contained large masses of colloid. There was a mucous polypus in the left antrum. The right lung was adherent to the chest wall; there was some perihepatitis, perisplenitis, and a well-marked hydronephrosis.

EXPLANATION OF THE FIGURES.

Fig. 1 is a sketch of the sinus (actual size), and illustrates the following:

(*a*) Empyema of the sinus. Thick, glairy, yellow pus was attached firmly to the posterior inferior wall, from which it extended to and through the ostium. The sketch gives a poor idea of the actual amount originally present, fixation having caused a very marked shrinkage, and handling of the specimen the detachment of a quantity of smaller particles.

(*b*) The pituitary fossa with its contained gland projects into, and is almost surrounded by, the cavity of the sinus. The importance of this anatomical relationship is obvious by inspection of Figs. 1 and 2. It has already been emphasized that actual bone does not offer so much resistance to the spread of organisms as might be supposed, this function being the property of, first, the sinus membrane, and, secondly, the dural periosteum on the other side of the bone. Hence we really have a condition in which the most important endocrine gland of the human body is suspended in a bath of pus.

(*c*) Macroscopic abnormality of the pituitary gland is evidenced by the abnormal appearance, which is irregular, and does not show the normal colour difference between the anterior and

posterior lobes, the anterior usually having a uniform reddish colour and being of loose texture, whilst the posterior part is firmer and considerably paler but uniform. The dividing line between the two lobes should be very narrow and distinct. In the present instance the pars intermedia is swollen, and contains masses of colloid. (In another case this colloid material has been shown to be associated with the presence of micro-organisms[2]; and in yet another case of our series, as yet unpublished, an enormous mass of colloid, almost as big as the pituitary gland itself, was found. The case was one of severe epilepsy, and the patient, who had recovered, was without fits for nearly a year before death.) The irregularity of the capsule and occurrence of adventitious fibrous tissue should also be noted.

Fig. 2 is a diagrammatic sketch superimposed upon the sinus to show the close relationship of the infected sinus and pituitary to that part of the brain concerned with various metabolic processes[3] (and which is often acutely involved in lethargic encephalitis). As the path of secretion is toward the brain stem it is obvious that toxic bacterial products in pituitary infections also find their way into this most important region of the brain, actual organisms having been demonstrated in the pituitary stalk of our case M. L.[1]

Fig. 3 is a photograph of the sinus membrane (Gram's stain). In the upper part of the figure can be seen ciliated epithelium, whilst the long, well-formed chains of a diplococcal streptococcus are below the surface. Although there was considerable pus in the sinus there seemed to be very little leucocytic reaction in the membrane, a point which must be emphasized, as it has an important bearing on the finding of the organisms still deeper in the tissues—either the organism seen was "non-pyogenic" or the biological immunity reaction by leucocytic inhibition was suspended. No other organisms were found in the sinus membrane. It has been said by an eminent histologist that granules in the tissues should never be taken for micro-organisms unless surrounded by cellular reaction. In the present instance undoubted streptococci are seen without even a lymphocytic reaction of any magnitude; *post-mortem* invasion can certainly be definitely excluded. This figure and all the remaining figures are direct reproductions from untouched photomicrographs.

Figs. 4 and 5 show the streptococcal chains in the submucosa and adjacent to the bone surface (black). Note especially that the morphological appearance of these still undoubted streptococci is now becoming less typical. The chain formation is distinct, but the size, shape, and spacing of the stainable part of the organism is distinctly irregular as contrasted with the diplococcal streptococcus nearer the surface.

Fig. 6 is a minute canal in the bone in which streptococcal chains are viewed "end on," the chain characteristic being verified by *the microscopical examination of successive horizontal fields.*

Fig. 7 shows streptococci in the vessel wall of the anterior pituitary, the arrows indicating a vertical and a horizontal chain respectively.

Fig. 8 shows the organisms adjacent to the eosinophile cells of the pituitary, the latter recognizable as large dark masses.

Fig. 9 shows small granules, in rows in the wall of the cavernous sinus, which are at least suggestive of their being partly digested streptococcal chains.

Fig. 10 is a vessel from the hypothalamus (stained by Gram's stain) showing granules in its wall, the significance of which, however, is as yet doubtful. The large dark mass consists of mucinoid material, which probably indicates a degenerative lesion of the nervous tissue in that region.

Fig. 11 is another vessel of the mid-brain showing a large collection of granules of varying sizes in its accompanying lymphatic space.

Fig. 12 shows a mass of spirochaetes, not syphilitic, but of the oral type, in the centre of a small lymphatic nodule adjacent to the upper part of the internal carotid, which was removed through the skull with the sphenoid block. Its interest lies in the fact that it clearly demonstrates the distance that a septic extension may proceed when the organisms are relatively avirulent and of the type usually regarded as non-pathogenic. Its *proximity* to the internal carotid may, given the assumption of a toxic or septic spread along the artery, explain the mental symptoms of confusion, since such spread would affect chiefly the cortical layer of the brain.

COMMENT.

The clinical picture suggested by the case is therefore that of a man having had an accident to the skull followed by infection, the nature of which remained obscure for years. Mental disorder was sufficiently marked to necessitate certification five, ten, and twenty-five years afterwards. The later finding of empyema of the sphenoidal sinus and otitis media strongly suggests that there had been an insidious chronic infective process of long duration involving both. We know from anatomical considerations that the carotid artery is in intimate relation both with the middle ear and the sphenoidal sinus.[4] From this it is obvious that the lymphatics accompanying the carotid would at least occasionally contain deleterious toxic products, and perhaps even on occasion organisms; such a condition, by an assumption of further distal spread by the wave-like arterial pulsation along the course of the carotid, would account for the cortical haemorrhages, especially that over the left fronto-parietal area, and also explain the mental confusion. The pituitary involvement renders impairment of the pituitary-hypothalamic region of the brain a logical conclusion. In view of the hydronephrosis one must consider uraemia in connexion with the status epilepticus, but it is noteworthy that in our collection of specimens with gross involvement of the sphenoidal sinus and pituitary most of them were epileptics, suggesting a more intimate relation between the status epilepticus and mid-brain disorder—in this case through the medium of an infected sphenoidal sinus.

A consideration of this case naturally suggests that pituitary disturbances should regularly occur when the infective process affects the tissues deeper than the membrane on the roof of the sphenoidal sinus. Well-marked cases showing such disturbance are often met with in general practice, and Ferreri[5] quotes a case with typical pituitary symptoms and early acromegalic signs which improved following drainage of the sphenoidal sinus. In such cases the pathological effects of the sinusitis presumably do not influence nervous tissue beyond the pituitary. It is not at all improbable, however, that in some cases there is a further extension to the brain stem via the pituitary stalk. The pituitary may not be affected in quite the same way as in the above cases, but a toxic disturbance of the pituitary secretion occurs leading to symptoms of hypofunction (with consequent overaction of other endocrine glands) rather than the more commonly recognized hypersecretion following irritation by tumour. In mental hospital cases there probably occur phases of hypersecretion and hyposecretion due to variations in the infection and resistance, leading to a disturbed balance of endocrine gland functions, which is a well-recognized feature of mental disease.

Gigantism, acromegaly, and dystrophia adiposo-genitalis are often recognized as occurring in mental hospitals;[6] but of much more importance in the present consideration are the *minor* changes which may occur due to dysfunction of the pituitary gland and the sympathetic centre of the brain with which it acts in various metabolic functions. The demonstration of such minor pituitary disturbances in mental hospital patients is difficult for several reasons. The co-operation of the patient is often wanting; the history, even from the patient's relatives, is deficient; the mental attitude itself of the patient demands such attention and study that minor endocrine signs and symptoms, though noticed, do not usually find their proper place in the clinical picture of the case; and also characters which we usually associate with pituitary disturbances are limited to those due to an irritation by a tumour of the pituitary rather than a toxic disturbance of its secretion.

Table I, collected from Schafer, gives various functions of the pituitary; Table II, from various sources, gives the nerve centres of the hypothalamus. These should be *studied* in conjunction with Tables III and IV, in which the symptoms of pituitary-hypothalamic dysfunction have been tabulated in 69 cases of insanity in which a pyogenic infection was clinically demonstrated in the sphenoidal sinus by Mr. W. Stirk Adams. The clinical symptoms were collected with the aid of Dr. T. C. Graves, Dr. Elizabeth Selkirk, and Dr. C. W. Forsyth, superintendents of the Birmingham mental hospitals. These tables afford evidence of the coexistence of metabolic disorder and mental disorder, the one often improving parallel with the other. It is also a matter of common experience that nearly every case of insanity where the pathological processes concerned are active, shows metabolic defects[3]; these are referable to the pituitary and hypothalamus acting as an endocrine nervous centre. It should be noted that, although the symptoms of refusal of food, delusions of poisoning, and abnormal hunger are at least partly referable to a disordered condition of the intestinal tract, they do afford *some* evidence for a coexisting disturbance of the function of the pituitary-hypothalamic region. It is therefore evident that a sphenoidal sinusitis may in certain circumstances affect the pituitary-hypothalamic region of the brain even although no *macroscopic* perforation of the pituitary fossa is present, such as occurred in the case M. L.[1]; this is supported by the comparison of symptoms and mental improvement which occurred subsequent to treatment following the demonstration of a pyogenic infection of the sphenoidal sinus in the 69 cases *investigated*.

WOUNDS OF THE HEART.

A STUDY OF THREE CASES.

BY

A. R. GILCHRIST, M.B., M.R.C.P.ED.,*

ASSISTANT PHYSICIAN, LEITH HOSPITAL; LECTURER IN THERAPEUTICS, EDINBURGH UNIVERSITY.

(From the Clinical Medicine Laboratory, Royal Infirmary, Edinburgh.)

WOUNDS of the heart have been recorded from classical times, and though they were then regarded as being invariably fatal, it is now well recognized that the heart is an organ which is able to tolerate mechanical interference reasonably well. Not only have wounds of the myocardium been successfully sutured,[1] branches of the coronary arteries ligated,[2] and foreign bodies extracted,[3] but in more recent years even the cavities of the heart have been explored in the hope of alleviating the mechanical handicap of a stenosis of the valve leaflets.[4]

TYPES OF FATAL CARDIAC INJURY.

While this is true, yet in war many combatants must die instantaneously from the immediate effect of wounds of the heart. In these days such injuries as result from the use of bullets, shrapnel, fragments of high explosive shells, and the like, are probably a more frequent cause of immediate cardiac arrest than statistics would indicate. Death, when it occurs instantaneously, is the result of a number of factors, notable amongst which must be the extent and severity of the lesion produced in the heart. The momentum of such missiles may be very great and the damage to the heart may be beyond all hope of repair. Sudden gross destruction with gaping lacerations of a wide area of ventricle or auricle is incompatible with life. Even a large proportion of the wounded in whom the damage is less severe must die before surgical aid can be made available, and in these shock and haemorrhage may be profound. Others, again, may survive a matter of minutes to hours, and die from the effect of the accumulation of blood within the pericardium. Blood leaking from a wound of

* Working under the Medical Research Council.

the heart muscle into the pericardial sac may raise the intrapericardial tension to a level approaching that in the great veins. The work of the heart is then greatly embarrassed by a decrease in the venous return, the systolic arterial pressure falls, and death results largely from mechanical causes. Such cases are eminently suited for surgical intervention. The risk of sepsis, secondary haemorrhage, and shock all tend to increase the death rate amongst those who survive the initial stages of the injury.

SURVIVAL AFTER HEART INJURY.

There remain to be considered those patients who survive the immediate effects of the wound, and in whom a bullet or other foreign body lies embedded in the myocardium for months or years. In such cases it is probable that the original injury was relatively slight, and that the missile, by acting as a plug, effectively checked any severe haemorrhage. It is the purpose of the following notes to record the effect on cardiac function of the presence of a foreign body retained in the heart muscle for a number of years. Three such have come under observation, and it was possible in two of the patients to study their cardiac functions thirteen years after the original injury, the foreign body being still *in situ*.

Similar cases have been mentioned from time to time in the literature. Apparently the first recorded observation of such a condition was made on the heart of a wild animal when, about the year 1600, J. C. Weber[5] described the finding of a bullet firmly encapsulated in the heart of a stag. A similar incident has been reported by Grainger.[6] "The animal was remarkably fat and healthy in condition," and had been wounded in the heart apparently some years before death, for the bullet was contained in a cyst in the substance of the muscle. That such a state is compatible with a long life is an old observation. Croly[7] mentions a Napoleonic veteran who was wounded in 1812 and lived for fifty-two years with a round bullet embedded within the pericardium. Delorme[8] quotes a case in which a bullet was found encysted in the wall of the right ventricle twenty years after wounding; the patient died of pneumonia. During the war years many similar cases came under observation, and, by the more general use of *x* rays, bullets and other foreign bodies have frequently been localized in the heart muscle. Vacquez and Bordet in 1918 were able to collect eight reported cases in which foreign bodies were situated in the heart and had not been extracted. A total of thirty-eight cases of war wounds of the heart came to their notice, and of these nineteen required surgical intervention on account of symptoms such as pain or dyspnoea attributable to the presence of the projectile.[9] Vance[10] has recorded three interesting cases of bullet wounds of the heart in which death resulted at a later date, and was not the result of the cardiac damage. In one of these the remarkable feature was the encapsulation of the bullet in the wall of the right ventricle with healed scars of the right auricle and lung demonstrating the route pursued by the missile in reaching its resting place. This man had been shot in the chest at least three years previously.

The older statistics[11] on the distribution of injuries to the heart show a much higher proportion in favour of the ventricles as compared with the auricles. The anatomical relation of the chambers of the heart is often considered a sufficient explanation of this fact, the ventricles presenting a larger surface to external injury. Moreover, the auricle walls are of finer texture and, being less substantial than those of the ventricles, suffer more severe damage from the lodgement of a missile. Greater laceration is to be expected in such tissue, and immediate death more probable. Statistics have been largely compiled from those cases surviving the initial injury. Mention is made of only four specimens of wounds of the auricle in the War Office collection of hearts,[12] whereas a great variety of wounds of the ventricle is shown in fourteen other specimens. In some of these the projectile had passed through the ventricles in its flight, in others it had embedded itself in the muscle, the degree of damage varying greatly. Sepsis was a fairly common complication in the specimens collected. Interesting observations on the localization of projectiles in the heart have been made by radiological examination. In a few instances the missile has perforated the muscular walls and remained free within a cavity of the heart. Whirling movements of the foreign body have been observed on screen examination; as though it were buffeted from side to side by the currents of blood within the chambers of the heart. Embolic phenomena have occurred on more than one occasion in such circumstances.[13]

While in certain cases surgical intervention for the extraction of a foreign body may be imperative, yet this is a procedure not to be undertaken lightly. If symptoms be in abeyance, then such objects as bullets or fragments of shell may well be permitted to remain innocent tenants of "the chief and most noble organ of the body."

CASE I.

A. R., now aged 35, was first seen on February 25th, 1928. He was wounded in France on August 18th, 1916. While standing in the trench he received a sharp knock on the back and then felt a sudden twinge in the region of the heart. He fell forward, but rose immediately, and after the application of a field dressing to the wound in the back he was able, a few minutes later, to walk a mile in comfort to the nearest dressing station. Later

FIG. 1.—Case I. X-ray photograph (6-foot plate) showing the presence of a spherical ball of shrapnel lying within the pericardium and dimpling into the ventricular muscle near the apex.

the same day he began to suffer pain in the region of the heart, and was transported to hospital at Etaples, being under the care of Dr. Nathan Raw. He was transferred to England, and was a patient in several hospitals. The question of operation was considered, but a surgeon consultant, who saw him in April, 1917, discouraged the suggestion and told the patient that no one could

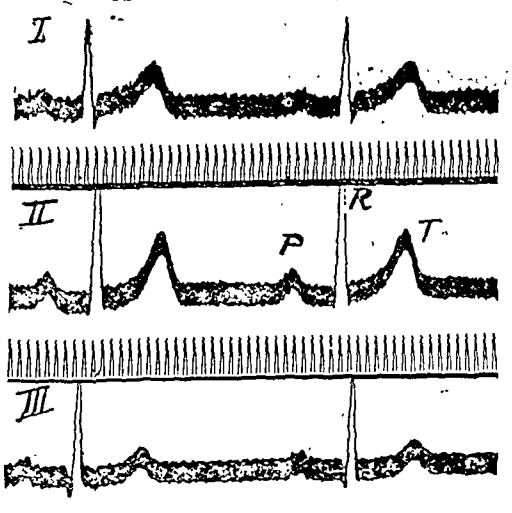

FIG. 2.—Case I. Electro-cardiogram showing the presence of normal sinus rhythm. The T waves are upright and well formed in all leads. The time-marker records 28.57 vibrations per second. 1 cm. deflection equals 1 millivolt.

guarantee him to be as physically fit without the bullet as he was with it. He was discharged on May 17th, 1917, and returned to civil life and his former occupation—a grocer's assistant. This man has been under observation for a year and has complained of no symptoms. He had had no previous illnesses of any importance, and had always been healthy.

Examination revealed a well-built, muscular man, 5 ft. 4½ in. in height and 10 st. 4 lb. in weight. There was a healed scar in the right interscapular region. The heart was not enlarged,

the apex being in the fifth space 0.5 cm. within the mid-clavicular line. The heart sounds were pure in character. The pulse was regular in rate, 64 per minute, and of good volume. The lungs were healthy, and no evidence of disease was detected. The skeletal muscles were rather flabby.

Seen again in February, 1929, he admitted that since the occurrence of the wound he had avoided all strenuous exercise, though he felt able for work, and could enjoy a round of golf without fatigue. He could play a game of football, but did not feel justified in making it a habit on account of the effort involved. He believed lack of training to be the cause of a bursting feeling in the head which he occasionally experienced after a game of football.

X-ray examination revealed the presence of a spherical ball of shrapnel lying within the pericardium and dimpling into the surface of the left ventricle above the apex (Fig. 1). Screen examination showed that it moved in a transverse direction with each cardiac contraction. A radiogram taken a year after the first examination demonstrated that the missile was in exactly the same position and had not "wandered." An electro-cardiogram taken on two occasions revealed no significant changes (Fig. 2). His vital capacity was 3,050 c.cm., being 73.8 per cent. of normal for his surface area.

CASE II.

J. B., aged 35, was seen in February, 1929. While serving in France he was wounded in the right foot at Hill 60 in 1915. After

FIG. 3.—Case II. *x*-ray photograph (stereoscopic view) showing the presence of two fragments of metal (A and B) within the chest. "A" lies in the hilus of the lung; "B" is smaller and is embedded not far from the apex in the posterior wall of the left ventricle.

treatment he rejoined his unit and was again wounded in July, 1916. He was hit in the chest, fell to the ground, and was rendered unconscious for some minutes. After being in hospital at Abbeville for fourteen days he was transferred to England, and was *x*-rayed twice at various hospitals. He experienced sharp stinging pains in the chest about this time, but is unable to recall any other symptoms. These soon cleared up and he returned again to France in October, 1916. He began to notice pain in the region of his heart, and on the march was more easily fatigued. After a further period of hospital treatment in France and England he was discharged from the army in June, 1917, and returned to his old employment—that of a mechanic.

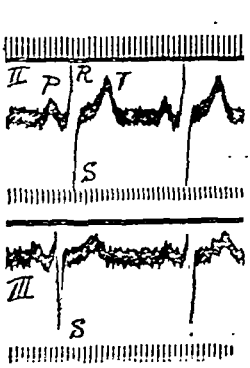

FIG. 4.—Case II. Electro-cardiogram showing the presence of normal sinus rhythm with a left ventricular preponderance. The T waves are upright in all leads. Time-marker and standardization as in Fig. 2.

In 1923 he began to have stomach trouble, and this has incapacitated him from time to time. He states that dyspnœa is only produced by sudden exertion. He lives in a top flat and has to climb four flights of stairs at least twice a day. A slight but definite degree of breathlessness is produced by this amount of exertion. He does not feel as able as formerly to lift heavy weights at his work, is sometimes dizzy, and has occasional pain over the eyes.

Physical examination disclosed a rather undernourished pale individual. His height was 5 ft. 7½ in., and weight 9 st. 8½ lb. The heart was regular in rate and not enlarged. The apex was 0.5 cm. within the mid-clavicular line. The sounds were pure and no murmurs were heard. The pulse rate after fifteen minutes' rest was 75. Blood pressure readings were 128 systolic, 94 diastolic. There was no evidence of disease elsewhere.

During the course of a routine examination a radiogram of the chest (Fig. 3) showed the presence of a fragment of metal buried in the left lung and another smaller piece in the wall of the left ventricle. It was noted on screen examination that with each heart beat the latter fragment moved to and fro in a transverse direction. Stereoscopic radiograms demonstrated that the fragment was embedded near the posterior aspect of the left ventricle. Another fragment was found in the left lung near the hilus. An electro-cardiogram (Fig. 4) showed the presence of normal sinus rhythm with a left ventricular preponderance. The vital capacity test gave a reading of 3,825 c.cm., being 92.7 per cent. of normal for his surface area.

CASE III.

This patient was a German soldier, aged 23, who died of a fat embolus in France on November 22nd, 1918, as a result of gunshot

FIG. 5.—Case III. Showing the heart, with a small block of tissue cut away to expose a fragment of metal embedded in the posterior wall. The thickened and adherent pericardium can also be seen. The missile is marked by the arrow.

wounds of the left leg and left arm. A *post-mortem* examination was performed the following day. The body was well developed. There was a large open wound across the middle and outer aspects of the left thigh with a transverse fracture of the shaft of the femur above the condyles. The ends of the bone were bathed in an abscess cavity. The left humerus was fractured just above the elbow-joint. There was also an entry wound over the spine of the fifth left lumbar vertebra, which was fractured. There was some extravasation of blood into the retroperitoneal tissue.

Besides these recent wounds, examination showed the presence of a well-healed scar of a wound sustained on a former occasion. It was situated behind the left posterior axillary line. The lower border of the eighth left rib was chipped. The inferior part of the pleural sac was obliterated, and the lung was firmly adherent to the chest wall and pericardium. The posterior surface of the heart was adherent to the pericardium. A fragment of high explosive shell was lodged in the muscle of the left ventricle, just below the transverse vein. It did not penetrate the whole thickness of the muscle. There was nothing else abnormal noted in the heart or other organs. The accompanying photograph (Fig. 5) shows the missile *in situ*.

The *post-mortem* evidence in this case indicated that the heart wound was obtained some time previous to the wounds which were the immediate cause of the man's death.

These cases are of interest in that they substantiate the view that the presence of foreign bodies embedded in certain sites of the heart muscle is compatible with an active and vigorous life. Just as a foreign body situated elsewhere in the body may give rise to no symptoms, so also may a small piece of metal in the myocardium be of no apparent disadvantage to its owner. This may be of

some importance from a medico-legal point of view. It also suggests that the immediate extraction of a foreign body from the heart is not always justifiable unless symptoms are urgent.

SUMMARY OF CLINICAL FINDINGS.

The electro-cardiograms show that the spread of the excitation wave through the heart muscle is not significantly altered in its course or time relations in these cases. It is well known that after infarction of the heart muscle certain changes may occur in the electro-cardiogram particularly affecting the form of the T waves. These alterations are more frequently observed when the lower part and apex of the left ventricle are involved in the infarcted area. The T deflection is said[14] to show a certain sequence of changes in shape and direction, gradually returning to normal as healing in the muscle takes place. It is possible that shortly after the injury sustained by the heart in the above cases, some deformity of the T wave might have been observed. After a lapse of years no abnormalities are to be detected in the T waves of these patients, even in the presence of inert metal buried not far from the apex. Apparently but few cases with retained missiles have presented themselves for electro-cardiographic examination. Lea[15] has recorded one instance in a young soldier with a fragment of shell embedded near the apex of the heart, in whom complete heart-block was present. In the single electro-cardiogram published the T waves were upright and of normal form. In the case of Jones[16] the T waves were inverted in lead 2 thirteen weeks after the injury. The left ventricular preponderance observed in Case ii of this series is not considered of much significance. The heart was not found enlarged or displaced by clinical or *x*-ray examination. Pericardial adhesions over the posterior surface of the heart might possibly account for this change.

The vital capacity test indicates that these men suffered from no diminution in ability to take a full deep breath. The test has been used to some extent as a measure of physical fitness, and has proved of value in following the course of heart disease. The fact that the result obtained in Case i was a little lower than might be expected is probably attributable to his voluntary abstention from most forms of physical exercise. The man was flabby and in poor physical training. In Case ii the high reading recorded indicates that, so far as this test is concerned, there was no impairment of his respiratory powers.

In Case iii it is assumed that, after obtaining a heart wound, this man was sufficiently fit to rejoin a front line regiment. Any cardiac disability under such circumstances is extremely unlikely. The man survived a heart wound, and must have led a vigorous life thereafter, ultimately to succumb to the effects of a compound fracture of the femur.

CONCLUSIONS.

1. Foreign bodies such as bullets, shrapnel, or fragments of shells may remain buried in the myocardium for years without the production of symptoms.

2. Two cases are described in which missiles were found embedded in the muscle of the left ventricle of the heart by *x*-ray examination thirteen years after wounding.

3. Both men are in good health and fit for active work at the present time, the foreign bodies being *in situ*.

4. The electro-cardiograms presented no significant alterations in the form of the T waves or other deflections.

5. In the third case, at *post-mortem* examination, a fragment of shell was found buried in the left ventricle. It was not related to the death of the patient.

My thanks are due to Professor D. Murray Lyon, who kindly placed Cases ii and iii at my disposal. The *x*-ray photographs were taken in the radiological department of the Royal Infirmary, and I am indebted to Dr. Woodburn Morison for the reduced prints. Case i was kindly sent to me for examination by Dr. S. Lapetz, to whom I am indebted.

THE TREATMENT OF NEPHRITIS.*

BY

ROBERT PLATT, M.D., M.R.C.P.,

MEDICAL REGISTRAR, ROYAL INFIRMARY, SHEFFIELD.

THOUGH nothing as dramatic as insulin, or as specific as liver extract in pernicious anaemia, has yet been applied to the treatment of nephritis, great advances have been made within recent years; and there comes a time when, with the gradual accumulation of new facts and theories, it is useful to review our knowledge of a subject, and bring our plan of campaign as far as possible up to date.

The more important functions of the kidney are: (1) The regulation of salt and water metabolism and the osmotic pressure of the blood. (2) The excretion of certain end-products of metabolism, especially from protein, and of other substances not required by the body. (3) The maintenance (with the help of other apparatus) of the acid-base equilibrium of the body. The first of these functions is represented clinically in the amount and specific gravity of the urine, and in the occurrence of oedema. With regard to the second function we have in the estimation of the non-protein nitrogen of the blood a delicate and important test, and one which is often most helpful in treatment and prognosis. It must be remembered that the normal kidney can, and will, excrete protein when required to do so—as, for instance, injected proteins, or haemoglobin when liberated from its normal position in the red cell.

The following classification of nephritis, based on that of Christian,[1] will be adopted in this paper.

1. Acute nephritis (oedematous, haemorrhagic, recurrent).
2. Subacute nephritis with oedema.
3. Chronic nephritis (*a*) with oedema; (*b*) without oedema; (*c*) vascular hypertension progressing into nephritis.

ACUTE NEPHRITIS.

Nearly every case of acute nephritis, whether oedematous or haemorrhagic, is a sequel of an acute infection, most commonly a throat infection, which it usually follows after an interval of ten to fourteen days. Scarlatinal nephritis, which in all cases is a sequel of a streptococcal tonsillitis, is no exception.

There are two factors at work in the production of acute nephritis: (1) the specific factor which causes the renal damage; (2) the factor of functional overstrain which determines the amount of the damage. Animal experiment[2] is quite clear on this point, for whatever the poison used—some of the recent work has been done with scarlet fever streptococcus endotoxin[3]—the amount of damage done by a given dose depends on the functional strain thrown on the kidney; in other words, on the amount of protein and salt in the diet. This applies not only to rabbits, whose normal protein intake is low, but also to animals normally carnivorous. A further point which stands out from the experimental work[4 5] is that fresh vegetables in the diet are not merely neutral in effect, but appear to have a positive influence in limiting the degree of renal damage.

The treatment of acute nephritis must therefore consist in the prevention of functional overstrain during the stage

* Abridged from an address given before the Sheffield Medico-Chirurgical Society, January 24th, 1929.

of acute renal damage, and the elimination of any existing source of further infection when the acute stage is over. The handling of the acute stage is therefore largely dietetic. The fluid intake is restricted wherever there is oedema, for if the kidney is retaining water it is obviously useless to give more water and so increase the oedema. Flushing out the kidneys is not only unnecessary and undesirable, but also impossible. The same principle applies to the treatment of the transitory anuria, which sometimes lasts for a day or two in the initial phases. If, as Volhard[6] suggests, this is due to a slowing down of the glomerular circulation brought about by congestion and oedema of the kidney, the condition is far more likely to be relieved by restriction of fluid, which will reduce the oedema, than by the administration of fluid, which will increase it. Cases of anuria in acute nephritis which I have treated by strict limitation of fluid intake have responded to their thirst by the recommencement of urinary secretion. For the rest, the diet should consist almost entirely of carbohydrate, with a minimum of salt and with a daily portion of fresh vegetable food. A limited allowance of milk is probably desirable, its small protein and salt content being compensated for by its value as a food in other ways. Milk as the sole or main article of diet in acute nephritis is, however, very far from ideal. These principles are represented in the diet sheet below:

Breakfast: Milk, cereals, tomatoes, bread or toast, marmalade.
Dinner Potatoes, green vegetables, Yorkshire pudding, milk pudding.
Tea Bread or toast with jam, plain fruit cake.
Supper Biscuits or bread, salad.
No salt or butter. Total daily allowance of milk 3/4 pint; other fluids 3/4 pint (water and fruit juice).

One cannot pass over the acute stage of acute nephritis without considering the treatment of convulsions. These are practically indistinguishable from eclamptic fits, and are presumably of the same origin. True uraemia is exceedingly rare in acute nephritis, though the only certain distinguishing test is the blood non-protein nitrogen. Following Volhard,[7] who believes that these convulsions are due to cerebral oedema, I have practised lumbar puncture in their treatment with success. Convulsions may add to the immediate gravity of the situation, but are usually relieved at once by lumbar puncture and have no effect whatever on the eventual prognosis.

By the end of a few weeks of dietetic treatment most cases will be free from oedema and haematuria, and there may or may not be some albumin remaining in the urine. If the patient is discharged at this stage he will either gradually recover entirely or develop subacute nephritis, or he will return very shortly with recurrent acute nephritis—a serious disease which in a certain number of cases again becomes subacute or chronic in type. These recurrent cases will, in my experience, all be found to have the same focus of sepsis which caused the first attack. The treatment of acute nephritis is therefore quite incomplete unless the septic foci have been thoroughly eradicated. To confirm this view I have been through the records of eighty-four cases of acute nephritis and have been able to follow up and re-examine fifty-four of them. The results are briefly given in the accompanying table.

Acute Nephritis.

	No of Cases.	No. Cured.	Percentage Cured.	Error.
Group I. No septic focus found ..	28	21	75	±20
Group II. Septic focus still present	12	3	25	±25
Group III. Septic foci found and removed	14	14	100	—

In the first group I found no obvious sepsis present on re-examination, but my search for it consisted merely of inspection of the tonsils and an inquiry into history of colds, sore throats, etc., and several cases of septic foci are probably included in this group. In the rest of this group the septic factor causing the original attack of nephritis was probably of a temporary or transient nature; 75 per cent. of these cases were well, and by this I mean that they had had no further attacks of nephritis, and had on re-examination no albuminuria or casts, no oedema, and no rise of blood pressure. Of the remainder, five have had between one and seven further attacks of nephritis, others have albuminuria or oedema still, with headache, malaise, and similar symptoms. In all cases it is at least a year since discharge, and although this is a short period, nephritis which is going to recur does so, in my experience, within six months (usually much less) of the initial attack.

The next group of cases all had obvious sepsis on re-examination, usually in the tonsils. They show a recovery rate of only 25 per cent. Of the rest, two are dead (one from subacute nephritis, the other from uraemia), the others show oedema, albuminuria, or both, or have had recurrent attacks.

Most of the patients in the third group were treated by tonsillectomy, and though the group includes four patients who had previously had two, three, or four attacks of nephritis, all are well to-day. It must be emphasized that but for this treatment these cases would have belonged to Group II, with the worst recovery rate of any.

The final column of "error" is based on the statistical formula $P \pm 3\ (0.6745)\sqrt{(Pq/n)}$; where P = proportion of successes, q = proportion of failures, and n = number of cases.

Subacute Nephritis with Oedema.

This oedematous type, known to older authors as the large white kidney, and now sometimes called nephrosis, is typically unaccompanied by cardio-vascular or retinal changes, or by nitrogen retention, and in many cases there are no casts in the urine. It arises insidiously and has only three essential features—namely, oedema, albuminuria, and oliguria. Sometimes, however, such conditions as raised blood pressure and nitrogen retention occur later in the disease, or are present from the first, perhaps because the nephrotic syndrome has been secondary to a true nephritis.

Before dealing further with the disease it is necessary to consider a few theories of oedema. The capillary wall may be looked upon as a semi-permeable membrane separating the blood from the lymph. Salts—that is, crystalloids—pass through the membrane, but not colloids such as the plasma proteins. An increase of intracapillary pressure (such as occurs in heart disease) will cause more fluid to leave the vessel, and hence will produce oedema; a reduction of plasma protein, by reducing the osmotic pressure within the vessel, will act in the same way. Such a reduction in plasma protein occurs in nephrosis owing to the prolonged action of a pronounced albuminuria. The effect of loss of fluid into the tissues will be to cause the kidney to excrete less water. Hence oedema and oliguria may both be dependent on albuminuria; and, remembering that the normal kidney can excrete protein, we see that the disease may be due to an error of metabolism whereby serum albumin can no longer perform its proper functions in the body, and is therefore excreted, just as sugar is excreted by the normal kidney in diabetes. This, briefly, is Epstein's theory of nephrosis,[8 9] and he has, in fact, lately named the disease "diabetes albuminuricus." Other interesting facts pointing to the general metabolic nature of the disease are the increase of lipoid substances in the plasma and elsewhere and the extraordinary tolerance of nephrotic patients to doses of thyroxin which would be sufficient to poison a severe case of myxoedema. The changes in the kidney are of a degenerative rather than an inflammatory nature (hence the term "nephrosis"), and may be secondary to the prolonged albuminuria. This has, in fact, recently been confirmed by the observations of Jungman,[10] who removed a portion of kidney from an early case and found it to be normal.

The present treatment, on which some of the cases, even after months of invalidism, may recover, apparently completely, is as follows:

1. The diet should be rich in protein and very low in fat.
2. Thyroxin should be given in large doses by the mouth, and, if necessary, intravenously. Epstein has given as much as 10 mg. intravenously.
3. Diuretics, such as ammonium chloride, calcium (possibly in conjunction with parathormone), and novarsurol,[11] have been used with some success.
4. Blood transfusion is rational, and useful as a temporary measure.

5. The removal or treatment of any obvious focus of sepsis is as important as in acute nephritis. I have seen one case in which the surgical drainage of an empyema was followed in six weeks by disappearance of albuminuria and oedema.

CHRONIC NEPHRITIS.

Chronic nephritis is a disease unlikely ever to become curable, though prevention may some day be within our power. The type with oedema is rare, and is a mixture of the previous and following types.

In the non-oedematous case there is nitrogen retention and high blood pressure, but no difficulty in water excretion. The indications in treatment are, therefore, restriction of activities and a low protein diet; but there is no need to reduce the fluid intake, and it is wrong to attempt to reduce the blood pressure by drugs, even if permanent reduction were possible. The high blood pressure exists to keep an adequate circulation through the diseased cerebral or renal vessels. It is surprising how often the onset of uraemic symptoms may be traced to a failure of the heart to keep up the high pressure. As the pressure falls the renal function becomes inadequate, and the patient dies of uraemia before he has time to die of heart failure. In all such cases the indication is to treat the heart and raise the blood pressure again; I have recently used pituitrin for this purpose, I think with some success.

URAEMIA.

In relation to the treatment of uraemia the following points are worth noting. (1) Patients with true uraemia occasionally recover temporarily and lead a more or less comfortable life for a few years. (2) Lumbar puncture is useful in convulsions, even in true uraemia. (3) Intravenous injection of glucose solution is probably more effective treatment than the older method of injecting saline. (4) Since the respiratory type of uraemia (so-called "renal asthma") is due to a true acidosis brought about by failure of the kidney to maintain the acid-base equilibrium, treatment by two-hourly administration of alkaline sodium phosphate in 30-grain doses, as suggested by Meakins and Davies,[12] is a rational procedure.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

HEROIN AFTER ABDOMINAL OPERATIONS.

THE interesting article by Mr. A. E. Mortimer Woolf, on March 16th (p. 499), tempts me to record an experience of my own.

A woman, aged 29, and in other respects perfectly healthy, was operated on by Mr. Geoffrey Bate for a twisted left ovarian cyst on March 22nd, 1928, at 9.30 a.m. Before the operation she received a hypodermic injection of 1/6 grain morphine and 1/180 grain atropine. No difficulties were encountered either with the operation or with the anaesthetic, which was administered by Mr. C. N. Chadborn.

At 3.30 p.m., as the patient complained of some pain, she was given, hypodermically, 1/12 grain heroin hydrochloride. The matron of the nursing home, feeling tired herself, sat down in an armchair after giving the injection of heroin, intending to rest in the patient's room. Half an hour later, hearing the patient grunt, she rose from her chair, and found her cyanosed and comatose, with complete cessation of respiration. Artificial respiration was started at once, oxygen freely given, and 1/20 grain of strychnine was injected hypodermically. When seen by me fifteen minutes later the pupils were small, but reacted to light, the corneae were insensitive, the respirations nine per minute, and the pulse good. Half an hour later the patient had come round completely.

There cannot, I think, be any doubt but that had the patient been alone in the room at the time, as might well have happened, she would have been found dead. The symptoms of poisoning were attributed at the time to an *idiosyncrasy, and I do not think were in any way* connected with the operation six hours earlier.

Personally I agree entirely with what Mr. Mortimer Woolf writes as to the dosage of heroin, 1/12 grain of which is nearly always an adequate dose, although the tendency in recent years appears to favour 1/6 grain.

Hove. DONALD HALL, M.D., F.R.C.P.

AN UNUSUAL CASE OF ECLAMPSIA.

THE case of eclampsia reported below may be of interest for the following reasons: (1) the strictness of the antenatal care throughout; (2) the unusual delay between the confinement and the onset of the fits; and (3) the large number of fits.

The patient, who was 26 years of age, came up for first examination in the twenty-fourth week of pregnancy. Her history revealed nothing of interest, though she had nursed two patients of mine with mild scarlet fever a year previously. She was a well-built country woman, and her urine was free from abnormalities. She was asked to report at monthly intervals.

At the next attendance (thirtieth week) there was a slight cloud of albumin in the urine. She was put on a modified protein-free diet and advised more rest, and told to report in a fortnight. This time the albumin had increased, and there was slight oedema of the feet. Blood pressure 150/110; fundi normal.

She was put on a strict milk diet and confined to bed. The following week the albumin decreased and the blood pressure was 140/90. The diet was maintained with the addition of carbohydrates, and she was allowed up for two or three hours in the afternoon. The next week the albumin increased again, and she was ordered back to bed, where she remained until her confinement, which took place a fortnight before full term. She had a remarkably easy labour, lasting only four hours, and was delivered at 7 a.m. on December 16th, 1928, of a healthy female child weighing 4 lb. 8 oz. The next three days were uneventful. She felt very well and the temperature and pulse were normal. She was still on a milk diet. Without any warning, at 5 a.m. on the morning of the fourth day after labour, she had her first fit. In all she had twenty-three severe fits.

She was removed five miles in an ambulance to the War Memorial Hospital, Melton Mowbray. Before removal she was given 2/3 grain of morphine sulphate hypodermically in two separate doses. On admission her stomach and colon were washed out with sodium bicarbonate; 2 oz. of castor oil were left in the stomach, and she had 2½ drachms of chloral hydrate, in 30-grain doses every two hours, per rectum. Venesection was performed and 15 oz. of blood withdrawn; 1/50 grain of nitroglycerin was given hypodermically. She was catheterized every eight hours. She had at six-hourly intervals 1½ pints, 1½ pints, and 1 pint of saline subcutaneously.

The urine at first was solid with albumin, but this has diminished every day. Her recovery has been uninterrupted. At no time has the fundus oculi been other than normal.

LEONARD J. HAYDON, M.R.C.S., L.R.C.P.

Melton Mowbray.

A COLOSSAL OVARIAN CYST.

THE following extraordinary case seems of sufficient interest to warrant recording.

A married woman was sent into hospital by Dr. Milburn of Kingston with a diagnosis of ovarian cyst. The patient stated that she had had a swelling for five years, but since Christmas it had increased to such an extent that she could hardly get about. She suffered little or no pain, no trouble with micturition, but much constipation.

On examination, I found that she was 4 ft. 10 in. in height, and her abdomen measured 56½ in. at the level of the umbilicus. There was no swelling of the lower extremities, her heart and lungs were fairly normal, but she looked like bursting at any moment. On February 2nd, under novocain, I made a small incision to the right of the navel and soon came upon the thickened wall of the cyst. I inserted a De Pezzer's self-retaining catheter with a clamp on the end, and had the fluid drawn off gradually at the rate of one gallon every two hours. Had I removed the whole cyst at one operation I feel sure she would have succumbed. On February 3rd the pulse, which had been rapid and somewhat irregular, had recovered, so I decided to operate. By a mid-line incision I removed the cyst, which was adherent over the whole surface of the abdominal cavity, and very thick-walled and multilocular, and non-malignant.

The thick brown fluid was very carefully measured, and amounted to 55½ pints. The patient made an uninterrupted recovery and left the hospital in eighteen days.

It seems very strange in these days that anyone should develop such a huge swelling without seeking medical advice. The amount is surely a "record" for so small a woman.

JOHN W. HEEKES, M.B., B.S.Lond.,
Surgeon and Gynaecologist, Royal Hospital, Richmond.

Reports of Societies.

THE PSYCHOPATHOLOGY OF ANXIETY.

A joint meeting of the Psychiatric Section of the Royal Society of Medicine and the British Psychological Society was held on April 9th to discuss the psychopathology of anxiety.

Dr. ERNEST JONES, opening, said that in psychopathology the term "morbid anxiety" was widely employed to designate a particular collection of phenomena, one which could be distinguished from those grouped under the name of fear. At least two factors served to make this distinction. The first was disproportion between external stimulus and response. In pronounced cases this was very evident—for example, in the claustrophobic distress induced by mere presence in a closed room, and, indeed, acute attacks of anxiety often occurred when it was impossible to ascertain any external stimulus of danger whatever. The second feature was disharmony between bodily and mental manifestations. As a result of general experience one allotted a certain degree of bodily disturbance to a certain degree of mental apprehension, and then noted that this proportion was in many cases deranged. This was easy to observe in extreme cases—for example, where a patient displayed extensive bodily disturbance of the kind associated with fear (dryness of the mouth, sweating, polyuria, and so on) and yet was very little aware of conscious fear. The greater prominence of bodily manifestations in cases of morbid anxiety as compared with those of normal fear was certainly very striking, and could not fail to arouse the impression of a thwarted instinct, as though some impediment to the usual expression forced the instinct to find an outlet in the bodily direction to a greater extent than would otherwise have happened. With regard to the pathology of the condition, the speaker thought the innumerable pre-Freudian hypotheses had now been discarded. Freud's first contribution to the problem was made on a purely physical basis. Studying the anxiety syndrome isolated in "neurasthenia" by Hecker, Freud separated it altogether from this disorder, and showed that it had a distinct and characteristic pathogenesis. The anxiety neurosis occurred whenever undue sexual excitation was combined with deficient opportunity for discharge. He laid stress on the element of frustration which was common to all the situations in which this neurosis arose, so that the anxiety could be described as what was found in frustrated libido. Freud assumed that in sexual excitation certain chemical substances were generated or liberated, and that when these could not be dissipated along their accustomed paths anxiety arose. The physiological basis of anxiety was generated from the physiological basis of libido by some unknown process of chemical transformation. Freud had refused to generalize from this finding, and he did not maintain that all anxiety had this source, only the morbid anxiety of the psychoneuroses. With the view that this morbid anxiety not merely arose in consequence of the repression of the libido, but was actually derived from it by some process of transformation, the speaker had at various times expressed disagreement, on the ground that there was insufficient evidence to justify postulating a process at such variance with the biological theory of instincts. He had suggested that the morbid anxiety was a perverted manifestation of the fear instinct, which, in the case of neurotic conflicts, had been stimulated to activity as a protection against the threatening libido. In his latest volume Freud had fully accepted this view, and abandoned his previous more complicated one. One was thus brought back to the simple conflict between ego and libido, in the course of which the former responded by developing a reaction of fear. Freud had further suggested that the developed dread sometimes found in situations of real danger was derived, not from the repressed libido that was directed towards external objects, as happened in the psychoneuroses, but from the narcissistic part of the libido that was attached to the ego. The speaker had applied this suggestion to the understanding of war neuroses, and had put forward the view, confirmed by others, that the only men who suffered from war shock were those whose libido, organized on a homosexual-narcissistic basis, was so attached to the ego as to become stimulated when the latter was threatened—that is, in situations of real danger. The mechanism of real anxiety in such situations was more complicated than might at first appear, and the speaker gave reasons for his description of the condition as a narcissistic neurosis, and fortified this conclusion by considerations drawn from allied fields. It was known that anxiety arose in relation to the over-development of a libidinal cathexis. The curious thing was that this could happen either from direct erotic excitation or from the opposite of this—namely, a threat to the libidinal organization. Apparently a threat caused a libidinal investment at the point threatened, as though the libido protected itself by increasing its strength. The speaker discussed the sense in which this relative excess of libido could be conceived as a danger, and entered into speculations concerning the function of the resulting morbid anxiety. He also instanced Freud's suggestion that many of the most characteristic features of anxiety would appear to be copied or perhaps even derived from the event of birth itself, in which bold and far-fetched suggestion Freud had been anticipated by Erasmus Darwin.

Dr. H. YELLOWLEES offered some considerations on the matter with special reference to the psychoses. The present conception of morbid anxiety, he said, was due to Freud, who was the first to unify its protean manifestations and to demonstrate them as the syndrome of the morbid condition. His theories and those of his followers as to the causation of anxiety states seemed to the speaker to require only intelligent and unprejudiced first-hand study to be accepted as sound by any reasonable physician. They were confirmed by clinical experience, and formed a reliable basis for effective treatment. The role of morbid anxiety in the psychoneuroses was obviously of very great importance. It played some part in practically all of them, a leading part in most, and in many it was actually the entire illness. The general opinion among many leading writers appeared to be that evolutional melancholia was the only psychosis in which anxiety played anything like a prominent part, but here it did so almost invariably. Other writers, however, held the view that anxiety might merge into other psychoses as well. The views of the analytical school were that anxiety might appear as a symptom of any form of psychosis, though it was most prominent in climacteric melancholia and the alcoholic conditions, especially delirium tremens. The speaker believed these views to be mistaken ones, and he thought it was not very hard to show where the misunderstanding had arisen. The word "anxiety" did not mean the same thing to the different schools. Freud gave the word as a psychological term and had every right to attach his own meaning to it. Freud gave an astonishing variety of detailed symptoms which he enumerated as possible manifestations of morbid anxiety, but in spite of this he offered a picture of something which, with a little care, and after a little experience, was not really hard to recognize, and that something, the present speaker submitted, was one with which the true psychosis had little or nothing to do. The morbidly anxious patient exaggerated mere possibilities, and used them as pegs on which to attach his anxiety. But it was a fallacy to think that any extension of this mechanism would lead to the delusions and dreads of the melancholic. Situations which would put a normal person in suspense left the psychotic unmoved. He had not found any psychotic whose symptoms were affected by bombing in air raids; in fact, he knew of no better aid in differentiating neurosis and psychosis than the effect of an air raid. He suggested that one would look in vain for the anxiety syndrome among psychotics. In the psychoses the role of anxiety, properly so-called, was a very subsidiary one. Borderline cases existed, but were not often to be found.

Dr. BERNARD HART said that the transformation of libido into anxiety was conceivable chemically, but as a biological conception it ceased to be intelligible. The conception that anxiety was a reaction of the ego, a striving to

protect itself against libido, was very fruitful, simply because it brought the conception of anxiety immediately into relationship with fear and dread, to which it was obviously closely allied. Fear was the reaction of the ego to external danger, and anxiety was a reaction to internal stress. In both cases the ego was protecting itself. It was more illuminating, however, to say that the essence of the reaction was not so much this protection as the failure of an adequate protection. If the response to external danger was completely adapted fear was not evoked, and if the response to internal stress was completely adapted there was no anxiety. The speaker regarded anxiety and dread as identical in essential mechanism, as in both of them the ego was failing to master a situation. The essential characters of anxiety were apprehension, tension, and unrest, and these were clearly discernible in evolutional melancholia and in some of the acute alcoholic and other psychoses.

Dr. R. D. GILLESPIE referred to the difficulty arising from the wide range of meanings attached to anxiety. The term should be used only when there was a definite consciousness of fear, though even that would not be sufficient. There was a very definite condition of mental malaise or tension which might be more or less conscious, but so big as to be practically unknown to the subject. It would be better if this condition were given a term implying mental pain. States such as this were the outcome of conflict.

Dr. W. H. B. STODDART disagreed with Dr. Yellowlees that anxiety was a characteristic of all the neuroses, since many obsessional patients never showed the anxiety reaction. Why did the patient with evolutional melancholia exhibit apprehensiveness so frequently? It was when repression of the sexual instinct became greater with the advance of life that anxiety came into play. Such cases were much relieved by potassium bromide, which he regarded as an anaphrodisiac, diminishing the degree of libido, whether conscious or unconscious.

In some further discussion Dr. J. A. HADFIELD pointed out that there seemed to be an intimate connexion between anxiety states and disorder of the adrenals. Dr. KUBIE of New York thought it useful to distinguish between anxiety as a cause and anxiety as a symptom. The absence or relative infrequency of anxiety from the psychoses still left the problem as to what was the role of anxiety in the preliminary situation. Dr. T. A. Ross described an interesting case with anxiety symptoms, which was not one of sex repression, and could be traced back to childish terrors.

Dr. WILLIAM BROWN, speaking of shell-shock cases, said that sex repression might have caused disturbance in some of these, but in others the disturbance seemed to be adequately explained in terms of the instinct of self-preservation. Dr. Brown protested against the use of the term "libido," in relation to sex, as if it were something which could be repressed and had its own energy. Often it was a manifestation of the lack of the power of an individual to assert himself as he would like to do.

PAIN IN RELATION TO THE UPPER URINARY TRACT.

A MEETING of the London Association of Medical Women's Federation was held on March 26th, at the British Medical Association House, Tavistock Square, with Miss HUXLEY in the chair. Miss E. C. LEWIS gave an address on pain in relation to lesions of the upper urinary tract.

Miss LEWIS said that there were three varieties of abdominal pain caused by lesions of the kidney and ureter: colic; pain in the loin and mid-axillary region, due to lesions of the parenchyma; and pain at the outer edge of the rectus abdominis, at the umbilical level, caused by distension of the pelvis. Colic in its most severe form was caused by a stone in the renal pelvis or ureter. Some writers had thought that it was due to tension of the kidney capsule, others that it was a spasm of the unstriped muscle. Legueu's work on pyeloscopy seemed to support the view that there would be painful and vigorous contractions behind an obstruction, just as in the alimentary canal; oddly enough, stones in the calyces did not cause pain. Renal colic, however, did not always indicate the presence of a stone; similar attacks, though usually less severe, were caused by the passage of other foreign bodies, such as blood clots from a malignant growth, debris from a tuberculous kidney, or "showers" of crystals; also by irregular spasms in acute pyelitis and ureteritis, in Dietl's crises, and in crises of nervous origin. The differential diagnosis included biliary and appendicular colics, and those of intestinal and pancreatic origin. The radiation of urinary colic was fairly characteristic. The other varieties of pain were more difficult to diagnose; they were often not particularly characteristic of the kidney, and gave no help in distinguishing the different kinds of renal lesion. A heavy aching pain, often accompanied by tenderness, was associated with large kidney stones and with ureteric stones impacted above a stricture, or with those too large, or lying too obliquely, to be passed on; in these cases the patient was often unable to lie on the affected side. There were exacerbations due to superimposed attacks of pyelonephritis. A stone impacted in the lower end of the ureter caused vesical pain and frequency. In hydronephrosis, which was merely the evidence of obstruction to the outflow of the kidney, there was aching pain from distension of the pelvis and parenchyma and, in large tumours, from dragging on the nerves of the pedicle and surrounding structures. Often the smaller distensions were the most painful. A great number of movable and dropped kidneys were symptomless and required no treatment, others gave varying manifestations, nervous, or referable to the digestive system, including the curious one of jaundice when the affected kidney was on the right side. Some of these kidneys caused renal obstruction and infection, with either aching or colicky pain.

Tuberculosis and malignant growths were almost negligible in differential diagnosis, the former because the slight aching in the loin was overshadowed by the bladder picture, and the latter because pain did not occur by itself, but was a late symptom, haematuria being the early one. The simple acute infections were perhaps the most difficult to diagnose and deal with. The milder ones might be painless; often there was tenderness without pain. In more severe cases pain and tenderness in the loin, accompanied by fever, were the dominating features. In the fulminating cases the picture was more that of an acute abdomen.

Spasms, strictures, and kinks of the ureter, Miss Lewis said, had received more attention in America than in this country; according to Hunner they gave rise to protean manifestations. The pain, when present, was felt in the lower abdominal quadrant, since the lesion was generally situated in the last few inches of the ureter. There might be tenderness where it crossed the brim of the pelvis, and also below the broad ligament. The pain was apt to be intermittent; some patients were only troubled at night, some by day, others in the early morning. There might be a free interval lasting for months. In 75 per cent. the picture was that of bladder irritability. The accompanying kidney manifestations were those of the distention and infections caused by the obstruction. Unfortunately, examination of the urine was not always helpful, since it was said to be normal in 30 per cent. of these cases.

In the differential diagnosis of the chronic types of pain, lesions of the upper digestive tract need not be considered, since here there was no relation of pain to the taking of food. Acute perinephritis began just like acute renal infection, but the urine contained no pus, and kidney function was unimpaired. An inflamed gall-bladder was usually tender to pressure beneath the costal margin during deep inspiration. The pain of an appendix was rather more lateral than that of the ureter, and did not radiate in the same way. A lesion low enough in the ureter to simulate one in the uterine appendages would cause frequency. Calcified mesenteric glands must be remembered, and also radiation along the lower dorsal nerves, secondary to spinal or thoracic diseases.

ACUTE INTUSSUSCEPTION IN INFANTS.

A MEETING of the Devon and Exeter Medico-Chirurgical Society was held at the Royal Devon and Exeter Hospital on March 28th, with the president, Dr. COHEN, in the chair. A paper was read by Dr. J. DOUGLAS MURRAY based on eight cases of acute intussusception in infants.

Dr. Murray said that the cases occurred during a period of thirteen months; all the patients were males, healthy and robust, between the ages of 3 and 22 months. In six cases the children were less than 12 months old, and these were all breast-fed, with the exception of one child, who was being weaned during the week previous to the onset of the acute symptoms. The speaker called attention to the fact that information as to the ordinary feed of the infant was rarely forthcoming in the notes of hospital cases, owing to the acuteness of the condition and the desire to remedy it as soon as possible after the child's admission. In the six cases of children less than 12 months old careful inquiries as to diet were made at the time of the child's admission, and dietetic errors or alterations were proved to exist in each instance, in spite of the mother's statement that the child was breast-fed. Dr. Murray mentioned that inquiries by Fitzwilliams into the seasonal incidence of the disease had revealed the fact that the maximum number of cases occurred in March and December, and that there was a steady decline in the incidence of this condition during the summer and early autumn months, when epidemic diarrhœa was most rampant. Moreover, the majority of cases of epidemic diarrhœa occurred in children who were artificially fed, whereas acute intussusceptions affected for the most part healthy breast-fed children; there seemed, therefore, to be no justification for regarding acute enteritis as a predisposing cause of acute intussusception. Dr. Murray mentioned that two of his patients had died, each with hyperpyrexia; in each of these cases, and in these two cases only, could the intussusception be felt per rectum. Recovery had followed in the remaining six cases, which occurred in two children, each of whom had three intussusceptions during the period of thirteen months; there was never less than four months' interval between one intussusception and the next. In each instance treatment was by laparotomy, with manipulative reduction of the intussusception. The non-operative treatment of this condition was discussed, and it was mentioned that uncertainty as to whether complete reduction of the intussusception had been effected seemed to be an insuperable drawback to this line of treatment. Finally, Dr. Murray dealt with the etiology of the condition, and stated that he regarded hypertrophy of the lymphoid tissue in the lower end of the ileum, consequent upon intestinal irritation produced by some error in diet, as the chief cause of acute intussusception in infants.

The PRESIDENT mentioned two cases of which he had had personal experience. In the first the stools passed immediately after reduction contained a stub of asparagus; in the second the last portion could not be reduced, and had to be opened up; an inflamed appendix containing pus was found inside. Mr. CANDLER said that in his opinion an elongated mesentery was the primary cause, and that dietetic errors provided the stimulus. As regards diagnosis, he emphasized the importance of emptiness in the right iliac fossa, and remarked that in some cases the lump could not be felt without an anæsthetic because it was high up under the liver or lower ribs. Under an anæsthetic, however, the hand could be pushed up higher and the lump be palpated. Mr. LOCK drew attention to the lessened incidence of acute intussusception. Mr. WAYLAND SMITH thought that if a change of diet or a dietary indiscretion was the cause of intussusception one would expect a much higher percentage of cases. He agreed with Mr. Candler that the underlying condition which made an ileo-cæcal intussusception possible was a congenitally long mesentery.

Dr. MURRAY, in his reply, agreed that the cause of intussusception was a moot point, and that the most probable etiological factor was an error of diet in children with an abnormally long mesentery. He thought that the "signe de dance" was of doubtful value.

Reviews.

PROGRESS IN PSYCHIATRY.

DR. HENRY DEVINE'S *Recent Advances in Psychiatry*[1] forms a noteworthy addition to this well-known series. An author of a textbook of psychiatry is faced with numerous difficulties. The aspects of the subject are so many that it is little wonder that many authors prefer to keep their eyes closed to some of them and thus contrive to impart to their subject a superficial aspect of simplicity by the process of omitting from their reckoning all views which are not in conformity with their own, and which would therefore destroy the unity of outlook which they strive to attain. Many writers also who desire to be comprehensive content themselves with the enumeration of a multitude of theories without attempting to construct from them any sort of synthetic unity of outlook.

It is Dr. Devine's unique contribution to this subject, that he is not only widely comprehensive in his survey, but that he has sought for a common factor in each of the numerous theories advanced towards a fuller comprehension of mental disease, and has succeeded in devising from them a synthetic formulation. In a chapter devoted to psychogenesis in the psychoses this method of approach is clearly shown. The author here contrasts two types of delirious condition—one a fever delirium, a reaction to an infective agent, and the other a psychogenetic delirium occasioned by psychic trauma. He points out that although the important etiological factor in the fever delirium is undoubtedly the morbid organic state, yet the form and content of the delirium itself requires to be studied in its relationship to the emotional undercurrents of the patient's life. On the other hand, in the psychogenetic case, organic factors have also to be reckoned with, in the exhaustion and toxæmia and insomnia associated with prolonged anxiety, and thus the treatment must be both physiological and psychological, although the illness was excited by a psychic experience. The student must not fail to realize, says Dr. Devine, that he is dealing with neither a physical nor a mental disease, but rather with a condition which can only be thoroughly understood and adequately treated when both physical and mental causal relations are taken into account. Psychic and physical explanations only represent different aspects of the same reality.

Dr. Devine impresses on his readers the necessity of keeping in mind that the psychoses, like normal reactions, are the product of a number of mutually interrelated factors, both psychic and organic, and he demonstrates the various relationships which exist between disordered states of mind and such factors as a psychopathic heredity, metabolic disturbances, organic diseases, obscure infections, endocrine disorders, and morbid changes in the cells of the brain. Under the heading "Cerebral Inferiority" the author considers patients who are the subject of an inferiority of those very functions on which the integrity of the personality depends, and indicates the practical corollaries of Bolton's findings with regard to the deficient durability of the cortical neurons. In dealing with the causation of mental disease he points out that even where a whole group of cases can be attributed to a common pathogenic agent, there does not exist any direct, immediate, and invariable relation between cause and effect. General paralysis is instanced as only one of the many possible effects of the infection of the organism by the syphilitic virus, and general paralysis itself shows a great variability in respect to form, course, and outcome.

The author has divided his subject matter into five parts. Preceding these is an excellent introductory chapter dealing with the fundamentals of psychiatry. Part I is devoted to the consideration of toxic, infective, and somatic factors in the causation of the psychoses; Part II to the effects of somatic disease in psychotic subjects and a section on shock therapy and one on malarial therapy

[1] *Recent Advances in Psychiatry.* By Henry Devine, O.B.E., M.D., F.R.C.P. London: J. and A. Churchill. 1929. (5 × 8½, pp. 340. 12s. 6d. net.)

in general paralysis; Part III is concerned with the behaviour of the organism in mental disorders, and in this part the haemoclastic crisis, basal metabolism, and carbohydrate metabolism in the psychoses are dealt with. Biopsychic types are considered in Part IV, and the relationship of physique with psychological type is demonstrated. The contents of the concluding part include the psychopathic "unconscious," and psychotherapy in the psychoses.

There is a wealth of information to be had from these pages, skilfully presented and closely analysed. Needless to say, Dr. Devine has an exact knowledge of all the recent publications of any importance on his subject; and the bibliographical references provide all that is required. The book is one which we can heartily commend to the student, general practitioner, and specialist alike.

SURGICAL DIAGNOSIS.

A NEWCOMER to the well-filled ranks of surgical textbooks, Mr. C. E. SHATTOCK's *Handbook of Surgical Diagnosis*[2] is arranged under the headings of diseases, the diagnostic points of each being then given. Despite the fact that a very economical style of composition is used throughout, the book runs to nearly 700 pages—an indication of the thoroughness with which the subject has been handled. In systematic textbooks, with few exceptions, the matter is divided into diseases, followed by an account of the signs and symptoms produced, but as the order has to be reversed in practice it might appear that a textbook of diagnosis should start with signs and symptoms and lead up to diseases; the clear, concise, tabulated style adopted in this book to a large extent overcomes this difficulty by rendering the various signs and symptoms very ready of reference. Modern methods of diagnosis are well represented, although not to the exclusion of older clinical methods, but we could find no reference to ventriculography in the diagnosis of intracranial lesions. The neurologist will scarcely agree that "cerebral neoplasm gives a history of slow, steady progress for months or years without any period of improvement," in view of the fact that the clinical picture produced by such cases is so largely determined by the varying degree of surrounding vascular change. Illustrations are limited to radiograms, taken, for the most part, from McKendrick and Whittaker's *X-Ray Atlas*. Few authors realize how much radiographic detail is lost during process reproduction; such radiograms as those on pages 321 and 279, while probably excellent in the originals, have too little contrast to be of much value after reproduction. On the other hand, the photographs in the gastric and urinary sections are admirable. The book is one which the student will find of value, especially in his final year.

Books that have been established for long periods of time, provided always that each edition is efficiently revised, tend to develop a mellowness which is often absent in newer publications, and such is the character of the late Sir ALFRED PEARCE GOULD's *Elements of Surgical Diagnosis*,[3] revised by his son, Mr. ERIC PEARCE GOULD. It is forty-four years since this work first appeared, but the present edition is none the less quite up to date, references (perhaps rather too brief in view of their increasing importance) having been made to cholecystography and the use of lipiodol as aids to diagnosis. The classification of the matter in regions rather than under individual diseases is the best that could be adopted in a book intended to help the student to discover the nature of the lesion from the signs and symptoms presented by the patient. This arrangement makes the book a very readable one, especially as the author has steered clear of the tendency to prolixity, which this method of approach so often encourages. It is refreshing to find a large number of experiential paragraphs, which are missing from the ordinary textbook, as, for example, in the chapter upon head injuries: "The surgeon is more likely to overlook fractures that exist than to diagnose the injury wrongly when they are not present"—a salutary reminder to the novice. Omissions are few, but there appears to be no reference to Froyne's syndrome or to the use of ventriculography, a method of diagnosis meriting some notice, even if of limited application. The illustrations are restricted to half-tone reproductions of radiograms, and on the whole are well chosen; some, however, have fared badly during reproduction, and are on too small a scale to be of much value. The book runs to 730 pages, and the general get-up and type are good. The seventh edition is worthy of even greater success than has attended the previous issues.

GERMAN MONOGRAPHS ON TREATMENT.

MID-EUROPEAN medical textbooks are tending more and more to take the form of single-topic handbooks. The practitioner's guide to metabolic disorders[4] by Professor RICHTER of Berlin, in a series entitled "Monographs on treatment," is a good example of this. It is considerably better printed and produced than many Continental books we have read. Also the translation into English is easier than that of the average German manual. There are chapters on the treatment of diabetes mellitus, gout, obesity, metabolic anomalies, and diabetes insipidus. Throughout the instructions are given in clear, dogmatic, tabulated paragraphs, and many charts and diet lists appear. The notes on the treatment of diabetes mellitus include a note on synthalin, which has a place in the regulation of diabetes in middle life. The great value of spa treatment as a prophylactic against diabetes in the "tired business man" type is stressed, and recommended in established cases of obese, constipated, gouty, and melancholic varieties of mild diabetes in later life. Balneological treatment, with precise instructions about the various German cures, is likewise fully considered in the chapters on obesity and gout. A new preparation, "lipolysin," recalling "fibrolysin," is mentioned in the treatment of obesity of endocrine origin. But beyond this there is nothing new in the book, and indeed it has no pretensions beyond its title. But it is well worth perusal by English-speaking clinicians. Acknowledgements are made to van Noorden, and to Professor Umber, the well-known Berlin authority on metabolism.

A similar volume to the above is one on remedial measures against blood loss[5] by Professor CLAIRMONT of Zürich, and Professor von den Velden and Professor Wolff, both of Berlin, who are the general editors of the whole series, have assisted. This book is, of course, mainly concerned with the indications and technique of blood transfusion. Two methods, neither of them new, are fully described and illustrated. Failing blood transfusion the authors recommend saline infusion, and of this they give the rationale and methods fully. The book is quite up to the high standard of the series, but all the information it contains is readily obtainable in similar English publications.

CHEMISTRY OF POISONS.

AUTENRIETH's *Laboratory Manual for the Detection of Poisons and Powerful Drugs*[6] is a compendium of information on the chemical properties and reactions of poisons. Toxicology, as a branch of chemistry, is founded on exact science, but its practice is an art which requires long and laborious effort for mastery. Although no book can take the place of practical experience, it must be recognized that practical experience cannot be gained without the help of books; the number that may be needed will be more or fewer according to their several characters. Autenrieth's will help to diminish the number; it is the most generally

[4] *Wie Soll der Arzt in der Praxis Stoffwechselkrankheiten behandeln?* Von Professor Dr. P. F. Richter. Therapie in Einzeldarstellungen. Leipzig: G. Thieme. 1928. (5½ × 8½, pp. 78. M.3.60.)

[5] *Die Bekämpfung des Blutverlustes durch Transfusion und Gefässfüllung.* Von Professor Dr. P. Clairmont, Professor R. von den Velden, Dr. med. et phil. Wolff. Therapie in Einzeldarstellungen. Leipzig: G. Thieme. 1928. (5½ × 8½, pp. 78; 5 figures. M.3.60.)

[6] *Laboratory Manual for the Detection of Poisons and Powerful Drugs.* By Dr. Wilhelm Autenrieth. Authorized translation by William H. Warren, Ph.D. Sixth American edition from the fifth German edition, completely revised, with extensive additions. London: J. and A. Churchill. 1928. (Med. 8vo, pp. xxvi + 628; 60 figures. 30s.)

useful that we have seen. It provides the toxicologist with abundant help for the occasions when he needs a change of method, or must have recourse to an alternative reaction for the detection of the poison sought. A poison dispersed in the fluids or tissues of an animal body may present difficulties to the toxicologist that have never occurred in other encounters with the poison. Thus with certain of the rarer poisons, particularly those of ill-defined characteristics, it is not always easy to determine how they may be isolated and recognized; and, in cases when no more is known of such a substance than has been described by workers who have studied it in its original purity, it is evident that a wide gap remains to be bridged by the manual of toxicology. It is in this respect that the volume before us appears to excel, for it provides a copious fund of information from which the worker may draw to enable him successfully to accomplish his purpose. Many books on toxicology have been written since the first edition of Taylor's. Not many of these possessed an added merit apart from the description of newer substances. Autenrieth's book not only brings the subject up to date, but is likely to be regarded as a landmark in the literature of the subject.

GUY'S HOSPITAL REPORTS.

WITH its first quarterly instalment for this year the *Guy's Hospital Reports*[1] enters on its seventy-ninth volume, and shows the admirable vigour that has made this far the longest lived series of hospital reports. Dr. A. A. OSMAN, working with the aid of a grant from the Medical Research Council, continues his studies in Bright's disease by recording some observations on the incidence and diagnosis of the various forms of acute nephritis, based on an analysis of 388 cases admitted to Guy's Hospital from 1900 to 1927 inclusive. Of the three forms of acute nephritis—haemorrhagic, diffuse, and tubal (nephrosis)—the two first are equally frequent and both commoner than the third, and all three are more often due to tonsillitis and acute infections of the upper respiratory passages than to any other cause. In a further article, "Some problems concerning the etiology of acute nephritis," he pays special attention to the importance of the "soil," observes that scarlet fever is certainly not the most common cause of acute nephritis now, and, while admitting that the hypothesis is not absolutely proved, argues that acidosis is an important, if not an essential, disposing factor. In his report of a case of hydatid of the kidney, Mr. R. P. Rowlands points out the difficulties of diagnosis from hypernephroma. Dr. G. W. Rake writes on encephalo-myelitis as a complication of varicella, a subject of great interest both in connexion with the relation of herpes zoster and chicken-pox, and with post-vaccinal encephalitis. Dysphagia due to pharyngeal paralysis is discussed by Mr. W. M. Mollison, who records thirteen cases. Dr. R. D. Gillespie gives an account of the investigation into the symptoms and signs of fatigue and exhaustion which he carried out at the Phipps Psychiatric Clinic, Baltimore, when McCunn Research Scholar in Physiology of Glasgow University. In an article rich in references to the literature Dr. Robert Donaldson, the recently elected Sir William Dunn Professor of Pathology, records a case of haemochromatosis complicated by primary carcinoma of the liver. This is followed by the report of a case of haemochromatosis under the care of Dr. Hugh Barber of Derby, with a note on the microscopical appearances by Dr. G. W. Nicholson. Visualization of the bile ducts after an opaque meal in two cases at the New Lodge Clinic is described by Drs. J. F. Venables and P. J. Briggs with the help of good radiograms. In some notes on peptic digestion Dr. F. A. Knott emphasizes the efficiency of milk as an antacid, and shows the negligible influence of such acid fluids as lemon juice and vinegar on peptic digestion. On the basis of cases at Addenbrooke's Hospital, Cambridge, Mr. W. H. Bowen discusses the etiology of appendicitis; he concludes that stagnation in the appendix is very important, that a stercolith or blocking of the lumen probably determines a fulminating attack, that in an appendix disposed to inflammation intestinal infection is prone to cause an attack, and, in view of Hurst and Knott's work, that achlorhydria is an important disposing factor. Dr. Maurice Campbell, writing from the cardiographic department, follows up previous work by giving his results on the vital capacity of forty cardiac patients who had been long under his observation.

[1] *Guy's Hospital Reports*. Vol. 79 (Vol. 9, fourth series), No. 1, January, 1929. Edited by Arthur F. Hurst, M.D. London: The *Lancet*, Limited. 1929. (6 × 9¾, pp. 126; 15 figures. Annual subscription, £2 2s.; single numbers, 12s. 6d. net.)

NOTES ON BOOKS.

"A MANUAL of tropical diseases and their care for nurses" would perhaps better describe the handy volume entitled *Tropical Nursing*,[8] by Dr. A. L. GREGG. The author has in a striking manner brought together into small compass the salient points of all the commoner tropical diseases—definition, cause, diagnosis, treatment, and nursing. Such a book is a new departure and will fill a much-felt want. In preparing for future editions, which will doubtless soon be needed, one would like to see the text carefully scrutinized for some ambiguities in phraseology, for essential details lacking here and there, and for a few minor inaccuracies. As examples, "Milk and butter should be stored in an ice-chest." How stored when no ice available? "Drink large quantities of fluid." When? In blackwater fever, "on no account sponge the patient's body unless hyperpyrexia occurs and the temperature exceeds 107° F." This statement needs some modification. To include gonorrhoeal proctitis and haemorrhoids as causes of dysentery is misleading. These, however, are minor blemishes that can easily be corrected in the course of revision.

The volume on *General Medicine*[9] of the Practical Medicine Series (1928) consists of five parts. In the survey of recent work on infectious diseases, which, as in previous years (see *Journal*, February 12th, 1927, p. 292), is undertaken by Dr. George H. Weaver, assisted by Dr. T. T. Crooks, the writers emphasize the number and importance of infectious diseases originating from animals. Diseases of the chest, excepting the heart, but including tuberculosis, are discussed by Dr. Lawrason Brown. Dr. William D. Stroud deals with diseases of the heart and blood vessels and diseases of the kidneys, and Dr. Ralph C. Brown reviews the recent literature on diseases of the digestive system and metabolism.

Dr. TINDAL'S *Gleanings from General Practice*[10] is an attempt by a practitioner who had to enter medical life when still little more than a boy, to assist younger men with "tips" learnt from experience or taught by colleagues. He instils into the young practitioner the duties of self-discipline, the habit of observation, and the right conduct of professional relationship. Hints on some general principles in medical treatment, and on the care of children and the aged, are followed by notes on cookery, on sick-room administration, and on useful remedies. There is very little that is new in the book or unobtainable from other sources, and some of the suggestions in treatment seem open to question. Is it, for example, "undoubtedly a good plan in every routine case of sickness to begin by ordering the patient to take a dose of laxative medicine"? and to advise patients to take this before sending for the doctor may be thought in some cases to be courting disaster.

A second edition of *Tuberculosis and How to Combat It: A Book for the Patient*,[11] by Dr. F. M. POTTENGER of Monrovia, California, originally brought out in 1921, and then noticed in these columns (1921, ii, 799), has not undergone much change. A new chapter entitled "The Will to Get Well" briefly insists that this attitude of mind makes it easier to bear the restrictions and self-denial necessary to attain benefit and cure, and remarks that without this help from the patient the guidance of the ablest physician may fail to prevent a simple case of tuberculosis from drifting into an incurable condition. As is pointed out in the chapter on the importance of treating early tuberculosis seriously, it is neglected tuberculosis that kills. Speaking from twenty-five years' experience in the treatment by sun baths, the author says that, as there are times when this is contraindicated, it ought not to be employed except under medical supervision. Clearly written, this book is a trustworthy guide to the tuberculous.

SATURDAY, APRIL 20TH, 1929.

DEFECTIVE PUBLIC CLEANSING IN THE LONDON AREA.

"COMPLAINTS have been made from time to time with regard to the disposal of refuse from London. In 1925 a deputation from the London County Council urged upon the Minister, among other matters 'the need for investigation by the Ministry of Health of the question of the disposal of house and other refuse.'" When so august a body as the London County Council becomes complainant to the Ministry of Health one is prepared to discover grave occasion; but not even the exalted powers that moved and were invoked will prepare the reader for a document at once so important and so disquieting as that which has resulted from the Minister's direction to Mr. J. C. Dawes to report on the general question of public cleansing in London.[1]

It is an axiom of physiology that only when the eliminative functions are adequately performed can the life of an organism be regarded as healthy. Accumulation of the end-products of metabolic activity is poisonous to the tissues in which they originate, and excretory defects are inevitably followed by a debasement of all other vital processes. This law is not limited to the animal economy; it operates also in a community of human beings—a military camp, a settled society, a town, a village; it may, indeed, be said to constitute the principle underlying the practice of hygiene. The art or habit of communal cleanliness has been very slowly evolved, and when attained is apt to be held insecurely. Mr. Dawes's report is a revelation of sanitary failure such as in these times we are little prepared to receive. That the system of public cleansing administered by the metropolitan borough councils is expensive, costing the ratepayers of London, as it does, some £2,200,000 a year, will cause little surprise. But though the long-suffering public is prepared to submit to exactions which are the price of efficient service, we are mistaken if it will tolerate a conjunction of high charges and bad service, particularly in matters in which its civic pride is deeply involved. London, proud of the healthiness it has secured for itself, and of its acknowledged place as the most hygienic city in the world, will be shocked at the shortcomings of the sanitary administration on which it has relied to safeguard the great health interests with which it has identified itself. "It cannot be too strongly emphasized," states Mr. Dawes, "that the cleansing service in any borough or district can be administered with certainty of economy only where there is in operation a complete and reliable costing system, designed to isolate uneconomic methods." Yet so unsatisfactory is the control of the collection and disposal of refuse that "the vital economic matter of detailed unit costing is not practised in any of the twenty-nine boroughs." "On the numerous boundary roads between boroughs refuse collection vehicles belonging to two different authorities are regularly to be seen engaged on precisely the same kind of work on different sides of the same road." "No borough within whose area another borough has erected disposal works has itself a disposal plant, so that we have the position of one borough regularly sending refuse into an adjoining area for disposal while the local council forwards the whole of its own refuse into some other local authority's area for disposal, probably a considerable distance outside its own borders."

Perhaps the most startling revelations in the report concern the festering masses of muck which have been permitted to grow into gigantic heaps along the banks of the lower Thames. These heaps arise from the indefensible and unhygienic practice of dumping the crude refuse of London on the river bank. One alone of such heaps measures some three-quarters of a mile in length, perhaps a third of a mile in width, already at one point 90 feet in height, and is extending rapidly in the direction of the Tilbury Road and the Beacontree Housing Estate. On this dump "about 150 men are regularly employed; there are ten steam-driven cranes for unloading refuse and ten locomotives to haul the loaded trucks to the tipping faces; probably a thousand or more tons of house and trade refuse, street debris, and other materials are daily dumped indiscriminately on them. . . . A scarred and fissured surface extending inwards for a considerable depth from the tipping face is evidence of extensive and deep-seated fire which frequently—one might almost say regularly—reaches up to the surface and envelops the great malodorous mass in a characteristically evil-smelling cloud of smoke." "From my inspections," says Mr. Dawes, "I am satisfied that these and all the large uncovered riverside dumps are extensive fly-feeding belts, and there is evidence to show that the amount of rat infestation is very great. . . . I do not hesitate to say that the reeking masses at South Hornchurch taken together comprise the worst refuse dump in Britain and by far the biggest. . . . Once detached and separated from a populated area, they now constitute a disfiguring and damaging environment to a rapidly developing district, and the case against continuance on the present lines appears to me to be overwhelming when viewed from the standpoint of public health."

It seems incredible that such things should be within the area of Greater London, and that the outward drive of its expanding population should carry the homes of its working people into a vortex of such foulness as surely never before in the history of the world has been permitted to accumulate. It is a strange reflection that there exists apparently no public authority whose duty it is and whose powers are competent to prevent or remedy the evils of these vast dumps. Not only, then, are there defects in the sanitary services locally administered, but there actually exists no central authority responsible for tackling the sanitary problems of Greater London as a whole, of which refuse disposal is only one.

Mr. Dawes's remedy, if we correctly understand him, is the creation of an *ad hoc* authority representative of the vast number of local sanitary authorities which in the aggregate go to the making of Greater London. The water needs of London have been similarly met by the creation of the Metropolitan Water Board. Electricity, transport, police, are analogously dealt with. Problems relating to other health services such as main drainage and sewage disposal, and the control and co-ordination of the public hospitals when Poor Law institutions pass to the administration of county councils, are pressing for statesmanlike consideration and constructive solution. They are not strictly medical problems; they are problems of local government. But if evils such as

[1] Ministry of Health. *Report of an Investigation into the Public Cleansing Service in the Administrative County of London.* By J. C. Dawes, O.B.E., M.I.Mech.E. London: H.M. Stationery Office, or through any bookseller. 1929. 15s. net.

those exhibited in the report under consideration are to be overcome, if fundamental public health requirements are to be met, then a reconsideration of the problem of the local government of London, however gigantic may be the task, will have to be undertaken. It is certain that a public health scandal such as that disclosed in Mr. Dawes's report cannot be permitted to continue.

LOCAL GOVERNMENT ADMINISTRATION.

THE Ministry of Health has now issued to the councils of local government areas a circular which directs their attention to the Local Government Act, 1929.[1] The circular is in general terms, and is to be followed by others dealing in a more detailed manner with special points of administration. The Minister of Health begins by emphasizing the importance and far-reaching character of the changes which the Act effects, and enumerates the outstanding defects of the system of local government which it is designed to remedy. These are, in the main, the existence of local authorities with areas and functions overlapping one another and so giving rise to waste and inefficiency; the burden on country districts of roads whose use is largely for heavy traffic for places beyond their boundaries; the rigidity of those boundaries; the inequitable incidence of rates, especially on agriculture and industry; the chaotic relation between national and local contributions to local expenditure. Certain of the main principles underlying provisions of the Act—such as the enlargement of areas and the spreading of charge, and the assignment of functions and work to the most effective authorities—are then stated.

The later paragraphs deal in somewhat greater detail with four very important administrative points: (1) the new organization of Poor Law and public health work; (2) the co-option of experienced persons on committees and subcommittees; (3) the support of the work of voluntary associations (mainly those connected with maternity and child welfare, mental defectives, the blind, and, in Wales, the treatment of tuberculosis); (4) consultation with local bodies representative of the governing bodies of voluntary hospitals and their medical and surgical staffs. The third of these points is of considerable moment, and bids fair to give rise to relatively complicated negotiations and calculations which may have serious effects on the work done in some localities. No doubt the paragraphs of the circular in this section will have the anxious consideration of those more particularly concerned. The other three points are those which are dealt with mainly also in the "Memorandum with reference to Administrative Schemes" which has now been circulated by the Council to Branches and Divisions of the British Medical Association, to medical officers of health, and to others, and which was published in the *Supplement* of April 6th last (p. 77). There are no serious discrepancies between the views enunciated in the two documents, but this does not lessen the need for vigilance and appropriate action on the part of the medical profession in connexion with the preparation of administrative schemes by the councils of counties and of county boroughs. The Ministry's circular and the Council's memorandum alike point out that local authorities are required, in preparing their schemes for carrying out the work transferred to them from the Poor Law guardians, to have regard to securing that any assistance which can lawfully be provided otherwise than through the Poor Law, but by virtue of the Public Health and other similar Acts, shall be so provided; but while the memorandum urges that this course should be taken at once and wherever possible, the circular rather stresses the reasons why it has not been made mandatory. The Ministry's circular is clearly favourable to the exercise by councils of their powers of co-option, but seems to stress unduly the need for the presence of women on committees (a need with which the councils of authorities are already quite familiar) and the advantage of including on certain committees some of those who have had experience as guardians of the poor (which is obvious), while making mention only of the general powers of co-option which enable local authorities to appoint men or women who are not members of the councils on their Public Health Committees, and on any subcommittees appointed by those committees or by their Mental Deficiency Committees. The desirability of securing representation of the medical profession on such committees or subcommittees is not mentioned, and must therefore be pressed by the profession in each area.

The concluding paragraphs of the Ministry's circular are concerned with the co-ordination of hospital provision and use, and with the consultations which must be held before any scheme is decided upon. It is well to note the statement that "Mr. Chamberlain cannot but attribute the greatest importance to the proper carrying out of this section"—that is, Section 13. "In making the necessary institutional provision for the health of the people it is imperative that local authorities should establish the most cordial relations with, and should make the fullest use of the accumulated skill and experience of, the medical profession in regard to hospitals." It is even more gratifying to read the very important and significant final sentence: "It is the confident hope and expectation of the Minister that as procedure under Section 13 becomes established and regular, it may lead to wider arrangements for the fullest consultation between the local authority and the medical profession, not merely in regard to institutional accommodation and its use, but also in regard to those numerous developments in the health provision of the people which are implicit in the new organization laid down by the Act." The prospect so envisaged makes it all the more important that careful and well-considered steps should at once be taken towards the establishment of suitable consultative and advisory bodies in the several areas.

In connexion with the earlier and more general part of the circular, we may mention here a recently issued booklet, *Relief for the Ratepayer*,[2] by Sir Kingsley Wood. This is an admirably clear and effective exposition (of course from the Government's standpoint) of the general effects of the Local Government Act, 1929, which will be of interest and value to many who are not concerned wholly or primarily with its relation to public health. As Mr. Chamberlain says in an introduction: "In its working, local government touches the daily lives of men and women more frequently, its results are felt more quickly, its inconsistencies and injustices as well as its benefits are perceived more acutely, than the slower and more remote influences on national politics." It is important, therefore, for all to understand the changes which are now imminent in this sphere, and (as the Prime Minister says in a short foreword to Sir Kingsley Wood's exposition of the Act) to realize that the country "has within its grasp a powerful instrument for the promotion of the national well-being."

RADIUM POLICY.

THE report of the Radium Subcommittee of the Committee of Civil Research has just been issued as a Parliamentary Paper.[1] From this we learn that the subcommittee was appointed on July 7th, 1928, and that its reference was "to examine the radium requirements of Great Britain in relation to the present sources of supply, and to submit recommendations." Its constitution was as follows: Lord Rayleigh (chairman), the President of the Royal Society, the Chief Economic Adviser to the Government, the Master-General of the Ordnance, the Director of the Geological Survey of India, the Chief Medical Officer of the Ministry of Health (Sir George Newman), the Secretary of the Medical Research Council (Sir Walter Fletcher), the Government Chemist, the Secretary of the Department of Scientific and Industrial Research, together with assistant secretaries of the Department of Health for Scotland, the Colonial Office, and the Ministry of Health. The report bears date March 7th, 1929, and is divided into nine sections. The first section describes the procedure adopted during the inquiry; the second discusses the new importance of radium in medical treatment; the third describes the existing supply of radium available for medical treatment in Great Britain and the methods adopted for its distribution; the fourth estimates the amount of radium at present required for medical purposes, and the fifth the relatively very small amounts required for the Fighting Services and for physical research; the sixth indicates the sources of radium production throughout the world, and the seventh discusses the cost of production and the price of radium. The eighth section outlines a proposed organization for the distribution of a central stock of radium for medical purposes, and the ninth summarizes the subcommittee's conclusions and recommendations. This eagerly awaited report is a document of great medical interest and importance, of which we shall publish a full account next week: we can only give now, while going to press, an outline of the final section.

The subcommittee's conclusions, in brief, are as follows. Knowledge of the properties of radium for the treatment of cancer and of the technique of its application has advanced very rapidly in recent years, and an increasing amount of radium is likely to be required for medical purposes in Great Britain. The Government's stock which is available for these purposes is 2.2 grams, while the amount belonging to hospitals and private practitioners is estimated at about 22.7 grams, making a total of nearly 25 grams. To meet present needs some 50 grams in all are required (that is, an immediate addition of about 24 grams to the existing national stock), but owing to lack of trained personnel and the inadequacy of existing hospital accommodation probably no more than 20 additional grams could be effectively absorbed for medical purposes by the end of 1930. Full advantage can be obtained from a given quantity of radium only when it is constantly in application—namely, when it is transferred from one patient to another with a minimum of delay—and such conditions are only to be found in centres with the necessary specialist personnel, technical equipment, and available beds. There is at present no common policy between the hospitals in acquiring radium, existing private stocks having been acquired for particular localities without reference to the needs of the country as a whole. A central stock of radium and some systematic method for its distribution are urgently needed. At present the Belgian Congo is the only source from which additional supplies for medical purposes are obtainable in any quantity. With adequate organization it should be possible to purchase radium at substantially less than the existing market price.

In the light of these findings and conclusions the subcommittee recommends that steps should be taken at once to acquire by instalments 20 additional grams of radium element for medical purposes; that a body entitled the National Radium Trustees should be appointed to hold the funds provided by Parliament or otherwise, and to purchase therewith and hold radium for use by a body of experts to be called the Radium Commission. The Trustees should consist of the Lord President of the Council, the Minister of Health, the Secretary of State for Scotland, the Presidents of the Royal Society, the Royal College of Physicians of London, the Royal College of Surgeons of England, the Royal Society of Medicine, and the British Medical Association, and the Chairman of the Central Liaison Committee of Voluntary Hospitals in Scotland, with two members to be co-opted later, if so desired, by the Trustees. The Radium Commission appointed by the Trustees should consist of a chairman (of distinguished public position, but not necessarily a member of the medical profession) nominated by the Trustees; four other persons nominated by the Trustees; and four representatives nominated, one each by the Minister of Health, the Secretary for Scotland, the Medical Research Council, and the Department of Scientific and Industrial Research. The powers and duties of the Commission should be "to deal with the custody, distribution, and use of all radium held by the Trustees, having regard to the advancement of knowledge, the treatment of the sick, and economy of use; and, in particular, to consider and approve plans submitted to them for the use of radium for the purposes of medical treatment and research, and to make the necessary arrangements for the supply of radium for such uses." Lastly, the subcommittee recommends that the Radium Commission should arrange with the National Physical Laboratory for the custody of the radium put at the disposal of the Commission by the Trustees when this is not actually in use for medical purposes, its preparation in form for use, and its recovery from such preparation on return from loan. In the body of its report the subcommittee records its conviction that the success or failure of this scheme, if adopted, will turn largely on the personnel chosen to form the Radium Commission, which should be composed of the best available experts in the several sciences underlying radium therapy, its membership being such as would enable it to work harmoniously both with the medical profession and with the Government departments concerned.

It will be seen from our Parliamentary Notes this week that on April 16th the Chancellor of the Exchequer said that the Government accepted the financial recommendations of the subcommittee. The purchase of 20 additional grams of radium before 1930 would cost about £200,000, of which the Government would contribute up to a maximum of £100,000, on the basis of £1 for every £1 privately subscribed. Mr. Churchill indicated that the Government had not yet decided upon the precise form of the holding and distributing bodies which would be set up to control the use of the 20 grams. He said that the subcommittee's recommendations on the subject of organization had been accepted in principle, but "the precise form of the organization will remain open to further discussion." The Government has been well advised to defer making any declaration of policy on this part of the report. It is clearly of great importance that the personnel of the Commission should be such as to inspire confidence both within the medical profession (on whose members will fall the task of working the proposed scheme) and among the general public (which is asked, directly by its benefactions and indirectly by taxation, to pay for it) that the radium purchased will be distributed to the best advantage.

A CONSERVATIVE BUDGET.

FINANCIAL policy has been the dominant factor in statecraft for the past decade, and practicability in terms of monetary resources the touchstone by which other policies have been brought to the test. It follows that a Budget produced on the eve of a General Election must exhibit with more than ordinary clearness traces of its political parentage. Mr. Churchill's well-earned reputation for independence of mind and courage has always created special interest in the unfolding of his financial proposals—an interest heightened this year by the probable effects on election prospects and by the current belief that this will be his last Budget. As is inevitably the case, he is accused of giving weight to considerations of electioneering strategy rather than of industrial policy. This, however, is an aspect of the question with which we have no concern. The annual Budget statement is not infrequently regarded as a long and comparatively prosy prelude to the brief announcements of forthcoming fiscal changes with which the statement closes. But the review of trade conditions, industrial progress or retrogression, national indebtedness, and other important factors in the health of the body politic will repay study. A Chancellor of the Exchequer has unique sources of information and advice, and his considered weighing up of indications of the future trend of events has special value. This is particularly the case with the present Budget, in view of the fact that Mr. Churchill was in a position to review the results of five years' practical study of national problems, and also because the nature and scope of the financial arrangements proposed necessarily indicate the means of approach towards the solution of other problems not mainly, or at any rate not exclusively, financial in their nature. Making appropriate allowance for the optimism natural in the circumstances, Mr. Churchill's review is distinctly encouraging. Increases in savings of the small investor class, decline in cost of living while money wages are being maintained, the transfer of purchasing power from the consumption of alcoholic liquors to the purchase of commodities or pleasures more conducive to physical and mental well-being, the improvement in the balance of trade, the rise in bankers' deposits, and other signs of increasing prosperity were touched on, and the conclusion is drawn that "the saving and consuming power of the people have maintained a steady advance." The road to industrial recovery proves arduous, and is encumbered by obstacles foreseen and unforeseen. All parties are alike desirous of arriving at the goal as quickly and with as little suffering as possible, but the methods of progress put forward vary considerably. The Labour party suggests that progress would be more rapid if some sections of the community would make greater sacrifices and put a more strenuous shoulder to the wheel, the Liberal party suggests that the time has come for some exceptional effort to reach the brow of the hill. Mr. Churchill's Budget makes it clear that the Conservative party regards the task as one to be achieved by slow and uncomfortable stages, lightened here and there by minor adjustments of the burden to be carried or by the removal of hampering restrictions, but incapable of rapid attainment by heroic measures. The financial proposals as a whole are clearly based on that assumption. They include one or two surprises, and will cause disappointment in some quarters. The most noticeable single proposal is the abolition of the tea duty, which absorbs over half of the margin of estimated income over estimated expenditure. There are, of course, many advantages in making a clean sweep of a particular tax instead of reducing it, including the greater convenience to traders and the financial saving that results from the scrapping of the machinery of collection; but the repeal of that tax has made a heavy inroad on the total amount available for remission. The financial readjustments in connexion with the brewing and distilling trade are somewhat complicated. On the one hand, these trades are to be required to pay over sufficient additional tax to compensate for the benefits they will receive under the de-rating scheme; on the other hand, a reduction in liquor licences payable by publicans and beerhouse keepers is given to an extent which will cost the Exchequer about twice as much as will be gained from the brewers and distillers. Seeing that most licensed houses are owned by the brewing companies, it is probable that a substantial part of the licence relief will sooner or later operate to benefit the brewers as landlords of the property. Time alone can show how these adjustments will work out, but at the moment the necessity for the changes is not very clear. The agricultural interest is benefited by the expediting of the de-rating proposals by six months, and agricultural land will now be freed from the burden of local rates as from April instead of October of this year. The railway companies are dealt with somewhat ingeniously; they are to be relieved of the Railway Passengers Duty on condition that the capitalized value of that relief is expended on improving their equipment, and in that way is passed on in part to industry generally. The amount expended on roads is to be increased, and other minor changes are made with a view to assisting various branches of industry—for example, the herring fishery trade is to be assisted by the reduction of harbour dues. The income-tax payer is left unrelieved. Mr. Churchill pointed out that this year the effect of the increased family allowances given last year will be felt to the full extent for the first time, and that he could not give further relief. The facts of the case bear him out only too clearly. Income tax now yields such enormous sums as compared with pre-war years that any substantial reduction would cost the Exchequer an amount which would be prohibitive. The income-tax payer's patience is passing into an adage, and he will have to continue to wait, with such shreds of hope as he can contrive to retain, until the weight of the war burdens has been perceptibly lightened or the recovery of industrial prosperity brings into view new harvests for the reaping of some enterprising and ingenious Chancellor. The 1929 Budget is no epoch-making or sensational document; it strikes us rather as an attempt to deal with the immediate necessities of the national position in a practical manner, and to provide opportunity for trade recovery in the future, not by speculative or heroic measures, but by giving as far as possible a fair field for individual effort and by distributing relief from taxation as widely as the circumstances permit. If caution be necessary in national finance—and history has several chapters on that lesson—then within the limits set by the facts of the situation Mr. Churchill seems to have grappled with his problems in a manner which deserves its full measure of praise.

LOOKING AT THE STOMACH.

SINCE the traditional case of Alexis St. Martin there have been attempts to make gastroscopy easy for the practitioner and for the patient, but it is doubtful whether the results obtained have justified the discomforts inflicted or the dangers involved. A simplified technique has been described in a recent pamphlet[1] by William Sternberg of Berlin, who uses a specially modified form of cystoscope and claims originality for his method, principally in respect of the position adopted by the patient. Anaesthesia is not recommended, general anaesthesia being, in his view, dangerous, and local anaesthesia demanding complicated apparatus and adding to the risk of the whole procedure. The use of sedatives such as morphine is condemned. Following the

[1] *Technique and Method of Use of Sternberg's Gastroscopy and Gastroscopic Treatment.* By William Sternberg, Berlin. London: John Bale, Sons and Danielsson, Ltd. 1929. (6 × 9½, pp. 19; 7 figures. 3s. 6d. net.)

usual preparations, which include attention to the hygiene of the mouth, washing out the stomach, and, to prevent steaming of the optical lenses, adjusting the temperature of the apparatus and the surroundings, the patient adopts the knee-elbow position, which, according to Sternberg, allows the maximum freedom of movement and enables the pylorus to be brought quickly into focus, and the gastroscope is passed. The exact technique of passing the instrument is set out in detail, but, as with most difficult manœuvres, it is probable that an actual demonstration would be easier to follow than a written description. Once the instrument is passed the patient is allowed to change his position in almost any way, the examiner following closely so as to bring various portions of the stomach into view. Finally, air, which has been introduced for the necessary distension of the stomach, is removed by means of a special two-way stopcock incorporated in the apparatus, and the tube is withdrawn by the patient again assuming the knee-elbow position and attempting to straighten his back, whereupon "the instrument practically drops out spontaneously." Sternberg has passed the instrument on one of his patients about 500 times in the course of four years to demonstrate a pyloric ulcer, but he emphasizes that he does not apply his operation to "patients" who are specially trained and paid for the purpose. This pamphlet gives a very clear idea of how the interior of the stomach may be visualized, but many reading it will wonder whether there is much to be gained by the procedure, and, in view of the condemnation of anaesthesia, whether there is any significance in the statement on page 7 that "it is . . . easier to perform gastroscopy on women and children than on vigorous men."

HARVARD UNIVERSITY CANCER CAMPAIGN.

THE sixteenth annual report of the Collis P. Huntington Memorial Hospital for Cancer Research and of the laboratories of the Cancer Commission of Harvard University covers the year ending June 30th, 1928. There was a fall in the number of new cases from 1,753 to 1,725; such a reduction has been anticipated for some time in view of the fact that other institutions for dealing with cancer cases are coming into existence in Boston. Mention is made in the present report of the collaboration of Dr. Mueller with Dr. W. E. Gye, both at Harvard and also in London. Although no complete agreement was reached with regard to the bearing of the data obtained by these joint experiments, a detailed report is to be issued later by Dr. Mueller. A number of interesting and important facts have been defined which, it is believed, will have a bearing on the whole subject of filterable viruses. Dr. Duane has been studying in Cambridge, Massachusetts, as well as at the Huntington Hospital, the accurate measurement of x rays for therapeutic purposes. A research assistant has been appointed under him to make a detailed study of the physical and chemical changes brought about in living tissues and chemical substances by exposure to x rays. A new and more powerful apparatus for the production of high voltage x rays has been designed by Dr. Duane and constructed. From November, 1927, to August, 1928, the treatment of cancer by the injection of colloidal lead was investigated, four beds in the research wards of the Massachusetts General Hospital having been set aside for this purpose; a final report has not been issued yet. The diagnosis service for the State Department of Health continued as in previous years, 2,519 specimens being examined, in addition to 824 specimens for the Huntington Hospital. In April, 1928, a cancer campaign was arranged under the auspices of the American Society for the Control of Cancer, the Massachusetts Medical Society, and the State Department of Public Health; in this the staff of the Huntington Memorial Hospital co-operated actively.

VACCINATION FOR BRITISH VISITORS TO FRANCE.

IT was announced in London on Tuesday, April 16th, that in consequence of the present outbreak of severe small-pox in England (referred to at page 742) the French Government, in application of the clauses of the Franco-British Convention of 1926 dealing with certain contagious diseases, had issued an administrative order requiring all passengers from British ports arriving in France after midday on April 18th either to produce a statement signed by a medical practitioner that they had been vaccinated within the past two months, or to be vaccinated on landing. On April 17th the British Embassy in Paris handed a note to the French Foreign Office urging that the order be suspended pending further consideration of the matter and consultation between the two Governments. At a meeting of the French Cabinet held on the same day M. Loucheur, Minister of Labour, stated that he had decided to accede to the British request, and that the British and French health authorities would meet forthwith and confer as to the best precautionary measures to be taken. He further stated that the suspended order had been issued by the local authorities of the Channel ports, acting under Article 42 of the International Sanitary Convention, and without previous reference to him. This is the situation as we go to press. The French Government has acted wisely in suspending a hastily conceived order, and it is likely that the health authorities of the two countries will speedily agree upon the most effective measures for preventing the spread of the present epidemic to France.

INTERNATIONAL SOCIETY OF SURGERY.

THE eighth Triennial Congress of the International Society of Surgery will be held in Warsaw from July 22nd to 25th, 1929. The subjects for discussion are the causes and mechanism of post-operative embolism, the results of resection of the stomach for gastric and duodenal ulcer, the treatment of exophthalmic goitre, and the reparative surgery of the hip-joint. The society has chartered a liner of the Compagnie Générale Transatlantique for the use of members; this will leave Zeebrugge on July 12th, and after calling at Ymuiden, Copenhagen, Riga, Helsingfors, Stockholm, and the Island of Gothland, will arrive at Dantzig on July 21st. Warsaw is within eight hours' railway journey from Dantzig. Messrs. Thomas Cook and Son are arranging inclusive terms for the stay in Warsaw and for the journey from London for those members who do not wish to join the preliminary cruise, with an extension to Vienna, Budapest, Prague, and Leipzig after the congress for those who desire it. As the hotel accommodation is limited early booking is desirable. The British delegate is Mr. J. E. H. Roberts (26, Harley Street, W.1), with whom intending participants should communicate.

ART EXHIBITION AT THE MANCHESTER MEETING.

BY the kindness of the Salford Corporation, it has been made possible to arrange for an art exhibition to be held at the Salford Art Gallery in Peel Park during the Annual Meeting of the British Medical Association in Manchester next July. It is proposed that this exhibition should consist of works of art (painting, sculpture, china, etc.) belonging to or executed by members of the profession, or having especially medical interest or association; and the Executive Committee will be glad to hear at an early date from any member willing to lend, or influence the loan of, any such work of art. The Salford Corporation has undertaken the insurance and transport free of cost to the lender, the only condition being that objects lent must be left on view for two months. All communications on this subject should be addressed to the Chairman, Local Entertainments Committee, B.M.A. Annual Meeting, 33, Cross Street, Manchester.

OPHTHALMOLOGICAL CONGRESS.

THE annual congress of the Ophthalmological Society of the United Kingdom was held in London, at the House of the Royal Society of Medicine, from April 11th to 13th, under the presidency of Mr. CHARLES HOWARD USHER. Each morning was devoted to short papers, about twelve of which were read and discussed, and there were two set discussions. A clinical meeting was held at the Royal Westminster Ophthalmic Hospital, and the congress concluded with a visit to the National Physical Laboratory. Concurrently with the congress an exhibition of ophthalmological instruments and apparatus was open at the House of the Royal Society of Medicine, and an interesting museum of historical and other exhibits was also arranged.

Ocular Tuberculosis.

A well-sustained discussion took place on the subject of ocular tuberculosis. Sir ARNOLD LAWSON, in opening, pointed out that this was essentially a surgical condition, and it was extremely uncommon to find it in relation with pulmonary phthisis. Infection might be extraocular or intraocular, and the former either primary or secondary. He used the word "primary," at the same time doubting whether tuberculosis of the conjunctiva could ever properly be so termed, but the diagnosis of this so-called primary condition could give rise to no confusion. The association of tuberculosis with interstitial keratitis might occur either as a mixed infection or as a pure tuberculous infection, but the former was much more common than the latter. The treatment of ocular tuberculosis had to be considered from two points of view: general and local. The general treatment included treatment on general constitutional lines, tuberculin, and phototherapy. Treatment by tuberculin had engaged much attention and brought out many differences of opinion. From his personal observation he was absolutely certain as to the value of this treatment, but care had to be taken that the case was suitable for its employment at all, for it was a dangerous remedy, and the proper manner of its employment, as to strength and frequency of dosage, was very important. On all these points the ophthalmic surgeon needed the advice of an expert physician. As to phototherapy, he could speak of its value with children, though not so positively with adults, but treatment must be carried out on closely supervised lines. In unskilled hands it was a dangerous method. The recent pronouncement of the Medical Research Council was based on the lack of evidence to support any claim for phototherapy to effect something which could not be effected by other less artificial means. The speaker thought the inference a little unjust, for he had never known phototherapy claimed as a means of treatment which would supersede good food, exercise, fresh air, and so forth; it was admittedly only a further addition to the resources of treatment.

Dr. R. A. YOUNG offered some observations on the diagnosis and treatment of tuberculosis in general, with only incidental reference to eye conditions. He expressed a good deal of scepticism with regard to the information to be obtained by specific tuberculin and serological tests. His own practice was to rely largely on clinical findings. As for phototherapy in treatment, he was convinced that where there was active or smouldering lung tuberculosis artificial sunlight could do harm. It could produce very much the effect of an overdose of tuberculin. On the other hand, he had witnessed its great effectiveness in the treatment of surgical tuberculosis. He had also used, though not for ocular cases, sodium morrhuate; sometimes this seemed to help, but at other times he thought it could do harm.

Mr. S. BROWNING, in speaking of the treatment of tuberculosis of the conjunctiva, mentioned that he had used bovine tuberculin almost as frequently as human tuberculin in eye conditions during the past fifteen years. He spoke of the difficulty of the diagnosis of intraocular tuberculosis, which depended on a tentative clinical diagnosis, backed up by bacteriological tests, and finally decided by a sort of trial and error treatment. While questioning as to how far one was justified in calling an eye condition tuberculosis because it improved under tuberculin, he had little doubt as to the value of tuberculin in the treatment of eye conditions which for one reason or another might be given the tuberculosis label.

Mr. A. L. WHITEHEAD expressed the belief that many cases with vitreous haemorrhages were of a tuberculous nature. He had had cases in which these haemorrhages preceded by some months any evidence of tuberculous infection. With regard to phototherapy, he thought it tragic to go to a clinic and find children sitting around the lamp, some of them getting badly burned, while others were receiving no benefit at all. Every case had a suitable dose, and it was an essential preliminary of treatment that that dose must be found for it.

Mr. W. S. DUKE-ELDER said that if ocular tuberculosis was of a surgical type a good response might be expected from ultra-violet radiation. He gave some account of three years' experience at the clinic at Moorfields, where light treatment was combined with tuberculin administration. In thirty-three cases in which there was reasonable certainty that the condition inside the eye was tuberculosis the result of the combined treatment was that in 85 per cent. of cases the eye became quiet after an average of five months' treatment; in 6 per cent. it was very much improved, and in 9 per cent. the disease was still active. Among the quiet cases there had been 18 per cent. of relapses, but these were readily controlled by a fresh course of treatment.

Dr. GEORGE MACKAY of Edinburgh was of opinion that the use of tuberculin ointment was well worth a trial as a substitute for the continued use of subcutaneous injections.

Minor Eye Injuries in Industry.

A report on the subject of minor eye injuries in industry, the economic loss they occasioned, and the means of their prevention, was brought forward by Mr. B. CRIDLAND of Wolverhampton. He showed statistics suggesting that, in spite of increased insistence on protection, the number of these cases was multiplying. Little information up to the present had been forthcoming as to the economic effect on industry of these minor accidents. Some attempt to answer the question in a limited area had lately been made by a subcommittee of the Council of British Ophthalmologists. Reports of minor accidents involving less disablement than a week had been collected from the casualty and out-patient departments of hospitals situated in certain special areas. The information related only to 426 cases. Rather more than half of these cases were in workers whose occupation involved exposure to very small flying particles (such as workers at grindstones), where the risk of serious injury was not great, the lesion almost always being a very small foreign body on the cornea. About a quarter of the total number were found in occupations involving exposure to chips of metal, and here there was risk of serious injury. The remainder consisted of a miscellaneous collection of occupations, the accidents being mostly foreign bodies on the cornea, with a certain number of abrasions and burns. Information as to protection was obtained in 406 of the cases. In 70 per cent. protection was not provided; in 19 per cent. it was provided but not used, and in 11 per cent. protection—goggles, machine-guards, etc.—was in use, but was evidently ill-fitting or inefficient. Some idea of the time lost was obtained: 371 of these cases involved a loss of from one to two hours; 48 of from two to eight hours, and 7 of from eight to forty-eight hours. The total working time lost in the 426 cases was 992 hours, or 124 days of eight hours each. There were three lines of prevention: mechanical guarding, education of the workmen, and reconditioning of the machinery so as to get rid of the flying particles. Goggles which were well fitting gave 100 per cent. protection.

The ensuing discussion turned upon the provision of protective appliances, several of which were exhibited in the museum. One speaker said that, after seeing the suggested goggles, he had every sympathy with the workman who decided to do without them and take the risk. Another suggested a vizor in light alloy, similar to the chain vizor used in the war, but of less heavy metal, and it was stated that one industrial firm at Bristol had provided for its

men a vizor made of black silk gauze, and that it was rather surprising how effectively this material intercepted foreign bodies.

Among other events of the congress programme were a discussion on heterophoria, opened by Mr. E. MADDOX and Mr. C. GOULDEN; a demonstration by Miss IDA MANN of the phylogenetic value of the lower retinal field; and a lecture by Mr. G. F. ALEXANDER, on the great antiquity of removal of cataract from the eye, and suggestions on the instrumentation of cataract operations.

Scotland.

Central Liaison Committee for Voluntary Hospitals.

THE Secretary of State for Scotland has appointed a committee, consisting of Lord Mackenzie (chairman), Mr. Charles F. Henderson, Provost Alexander M. MacEwen, Mr. James Macfarlane, Dr. D. J. Mackintosh, Major-General James Thomson, A.M.S.(ret.), Ex-Provost James Thomson, and Sir David Wallace, F.R.C.S.Ed., with the following terms of reference:

> To be for the period to March 31st, 1932, the Central Liaison Committee for Voluntary Hospitals in Scotland to act in liaison between the Department of Health and the Regional Committees of Voluntary Hospitals in Scotland, to assist in keeping the department in touch with voluntary hospital opinion, and, in the development of hospital services in Scotland, to foster co-operation between the voluntary hospitals and the local authorities in each region.

The minute of appointment formally reconstitutes the committee that was set up at the meeting between the Secretary of State and representatives of the Scottish voluntary hospitals in December, 1927. During negotiations on the hospital clauses of the Local Government (Scotland) Bill the committee suggested to the Secretary of State that the Liaison Committee would be strengthened for its work in conserving the voluntary system and promoting co-operation through the changes which will follow on the passage of the bill if its constitution and status were more exactly defined. The minute incorporates the committee's suggestions. The present members will hold office for three years, and future appointments will be made by the Secretary of State on the nomination of the Voluntary Hospital Regional Committees. The voluntary hospitals have set up regional committees in each of the five regions, with centres at Edinburgh, Glasgow, Aberdeen, Dundee, and Inverness.

Sir David Wallace is a director of the Royal Infirmary and other hospitals in Edinburgh, and chairman of the South-Eastern Regional Committee; Mr. James Macfarlane is chairman of the Glasgow Royal Infirmary and chairman of the Western Regional Committee, and Dr. D. J. Mackintosh, medical superintendent of the Glasgow Western Infirmary, and Ex-Provost Thomson, director of the Stirling Royal Infirmary, are also members of the Western Regional Committee; Major-General Thomson is a director of the Aberdeen Royal Infirmary and a member of the North-Eastern Regional Committee; Mr. C. F. Henderson is a director of the Dundee Royal Infirmary and a member of the Eastern Regional Committee; and Provost MacEwen is chairman of the Northern Infirmary, Inverness. Lord Mackenzie was chairman of the Hospital Services (Scotland) Committee which reported in 1926.

Report of the Scottish Board of Health.

The tenth annual report of the Scottish Board of Health, dealing with the year 1928, has just been issued. This is the last year in which a report will be submitted by the Board of Health, whose functions have now been taken over by the Department of Health. The report therefore includes a reference to some of the important developments that have taken place during the ten years of the Board's existence. The Board was instituted in 1919 as a combination of the Local Government Board for Scotland, the National Health Insurance Commission, the Highlands and Islands Medical Service Board, and the medical sections transferred from several other departments. The most urgent problem that confronted the Board on its appointment was in relation to housing, building having to a great extent been held up during the war. A majority of local authorities, in co-operation with the State, which offered subsidies, initiated building schemes whereby over 100,000 houses were erected for the working classes. In addition, about 2,000 houses have been built each year by private enterprise. These new houses afford a standard of comfort far in advance of that attainable in the smaller, more crowded, and less sanitary buildings of the past. The clearance of slum areas was a cognate task for which a Treasury grant to cover loss has been available to local authorities since 1923. The number of houses dealt with in this way has exceeded 14,000. Dundee, in consequence of a gift of £130,000 by Mr. Robert Fleming for the purpose of purchasing sites and rebuilding houses condemned as insanitary, has enjoyed special facilities for slum clearance.

Public Health Services.

The health of mothers and children has received sustained attention in recent years. The maternity and child welfare service, started during the war, has made great progress, and still continues to develop and demonstrate its usefulness over the whole of Scotland. The care of children in health and in sickness is covered by this service until they have reached the age of 5, when they pass to the supervision of the school medical service. The usefulness of the measures undertaken, which include home visitation by health visitors, provision of ante-natal centres, child welfare centres, and skilled midwifery service with institutional treatment when required, has been proved by the continued fall in the infantile mortality rate and in the death rate of children under 5 years of age. In Scotland there are roughly 350,000 children between the ages of 1 and 5 years, and it has been a common observation of school medical officers that a large proportion of the disabilities found in school children are discovered in those just entering school. Medical inspection and treatment of school children were in operation before the war, but the present system has only developed since the year 1919. There are approximately 825,000 pupils in the State-aided schools of Scotland, and in practically all areas these children are inspected at least three times during their school life. The Board has welcomed the recent movement to take children from the congestion of the towns, and protect them from the dangers of the streets and roads, by establishing and extending playing fields, and further recommends the provision of more adequate recreation facilities for persons of all ages. It makes reference to an investigation into the nutrition of school children carried out in the past two years by funds provided by the Empire Marketing Board. The investigation showed that milk is an invaluable food for growing children, and that those who received an extra ration increased in weight and height with special rapidity. After leaving school the majority of children come under the national health insurance scheme, which in Scotland includes 1,751,200 persons. The amount of money spent annually on various benefits to insured persons was nearly £4,000,000. Surpluses, disclosed by valuations of societies made within the past ten years by the Government valuer, have been made available for additional benefits, the greater portion having been spent on ophthalmic and dental benefits. Arising out of the industrial position of the year 1926 and subsequently, the heavy claims on national health insurance funds have caused grave concern, and until results of the third valuation, at present in progress, are known it will not be possible to forecast how far additional benefits will continue to be available. Among recent developments in the insurance scheme has been the contributory pensions scheme, which came into operation in 1926 and 1928; 1,774,100 persons have been insured for the purposes of contributory pensions, and the total number of beneficiaries is now over 173,000. The Highlands and Islands medical service scheme had brought within the reach of all persons in isolated areas the services of medical practitioners at modified fees, and a special development of the last few years had been the establishment of a surgical service for Lewis and Harris, Orkney, and Shetland.

Problems of Hospital Accommodation.

The report points out, in regard to the treatment of disease, that there still exists a shortage of hospital beds for the country as a whole, estimated in 1925 to amount to 3,600 beds. A movement to secure co-operation in hospital services has developed strongly in the last few years. The voluntary hospitals have set up area committees in each of the five hospital regions of Scotland to survey the needs of the areas, and, at the request of the Secretary of State for Scotland, a voluntary hospitals liaison committee has been appointed to act between the area committees and the central department. In Aberdeen a scheme for co-ordinating the poor law and public health services has been carried through with great success, the way having thus been cleared for co-operation between the public authorities, the medical profession, the university, and the voluntary hospitals. In Glasgow, Stirling, and Falkirk, also, promising experiments in co-operation between public authorities and voluntary hospitals are being carried out.

Infectious Diseases.

Compulsory notification of infectious diseases has been in operation in Scotland for about thirty years, and in the same period a movement for the establishment of hospitals for infectious diseases has matured. During the past ten years there has been no decided diminution in the number of cases of scarlet fever, although the disease has become milder and the death rate has fallen. In the same period cases of diphtheria have, on the whole, increased, but with a marked reduction in the proportion of deaths. In both of these diseases 75 per cent. of cases have been treated in hospitals. Enteric fever has shown an extraordinary fall to one-tenth of the previous number of cases, and an even more striking reduction in the number of deaths. The death rate from pneumonia has shown no decrease in recent years, but local authorities have recently opened their hospitals to more than 5,000 cases each year. Measles and whooping-cough have shown a diminution in the death rate for the past ten years.

Developments in Health Legislation.

In 1920 the Blind Persons Act placed on local authorities the duty of making arrangements for promoting the welfare of blind persons, and generally approved schemes were provided for carrying out such services through voluntary agencies. As a result the number of untrained employable blind persons has been steadily reduced, and nearly all blind children are being educated. Old age pensions have become payable to blind persons at the age of 50. With regard to general sanitation, considerable developments have taken place in the last ten years. The majority of burghs and townships were provided with considerable water supplies and drainage systems in the thirty or forty years before the Board took up office, but a provision in the Local Government (Scotland) Bill enables county councils to contribute towards the cost of water and drainage in villages and other places where sufficient money cannot be raised by assessment. Within the past few years great public cleansing services have been reviewed in many cities, and well-understood rules are now in operation to prevent nuisance to those who live in the vicinity of refuse dumps. Great interest is being manifested by the public in matters relating to diet and food, and food shops are tending to grow more attractive and more cleanly. In 1923 a uniform standard of meat inspection was established by the Board, and in 1925 the Preservatives Regulations were framed to deal with the addition of chemical substances to foods. The Milk and Dairies (Scotland) Act, which came into operation in 1925, provides control over milk to ensure that it should be clean and wholesome, and every dairy cow in Scotland is now examined by a veterinary inspector at least once a year, in some burghs even every month.

The report refers especially to the services rendered by Sir Leslie Mackenzie, M.D., who has now retired, and mentions particularly the measures initiated by him for the treatment of tuberculosis, the medical inspection and treatment of school children, and the care and supervision of mothers and young children.

Church of Scotland Deaconess Hospital.

The annual meeting of the Church of Scotland Deaconess Hospital was held in Edinburgh on March 22nd. The annual report showed that the number of out-patients had increased greatly in recent years, and the board hoped to acquire during 1929 a site adjoining the hospital for the erection of a building to enable them to treat a much larger number of such patients than the 6,893 who had received treatment during 1928. The number of patients treated in the wards during 1928 was 640, and the income during the year amounted to £6,031, with an expenditure of £5,899, which left a surplus on the year's working of £231. The chairman said that all institutions of that kind had their ups and downs, but few institutions could record such a small number of downs as the Deaconess Hospital, of which the reports had been almost uniformly reports of progress.

Ireland.

Medical Matters in the Dail.

IN connexion with the discussions on the estimates for local government and public health, most of the medical members of the Dail made contributions. Sir James Craig, M.D. (Dublin University), said that there ought to be a Minister, or at least a Parliamentary Secretary of Public Health, who had had a medical training. He was not finding fault with the present Minister, but there was no doubt that the sanitary condition of the country was unsatisfactory—in parts of the small towns and villages the conditions were deplorable, and they could have no stronger proof of this than in the fact that in one area there were seventy cases of enteric fever. He had never suggested that good sanitation would prevent small-pox, but enteric fever and diphtheria, the two infectious fevers now prevalent, were eminently diseases brought about by bad sanitation and bad water supply. What, he asked, was the use of sending medical inspectors to inspect conditions for which they could do no good? They would make no progress in the sanitary conditions of the country until they had appointed county medical officers of health, who would alone be responsible for that class of work. He would like to know what progress had been made in the medical inspection and treatment of school children, which was absolutely necessary if they were to have a first-class adult population. He had spoken before about the insanitary condition of the schools, which was a disgrace to the country. It would have been a godsend if these schools instead of the country mansions had been blown up, because they would have been replaced by proper buildings. Dr. O'Dowd (Roscommon) drew the attention of the Minister to the outbreak of typhoid fever in Carrick-on-Shannon, county Leitrim. Dr. O'Dowd stated that the water supply for the town was drawn from the River Shannon near the same spot where the sewage of the town entered the river. It was true that the water was filtered, but analysis showed that it was polluted. He appealed to the Minister of Local Government and Public Health to see that such towns as Carrick-on-Shannon were provided with proper water and sewerage systems. He also urged that a scheme of compulsory inoculation against typhoid fever should be enforced immediately in any district from which a case came. Dr. T. Hennessy (Dublin City, South), replying to a deputy from Mayo who urged on the grounds of economy that the dispensary doctors should be made to do all public health work in the Free State, said that it would be impossible for the dispensary doctors to carry out the duties of whole-time medical officers of health. Apart from any special training and administrative experience, the dispensary doctor, who was a part-time medical officer, was mostly dependent on his private practice, and if he rigorously discharged the duties of a medical officer of health it would bring him into frequent conflict with perhaps some of his best clients. Dr. Hennessy readily admitted that the Minister and the Department of Public Health did an immense amount of work for the promotion of public health administration in the Free State, especially when the ill-advised opposition they met with from some of the local authorities was borne in mind.

He objected to the position given to the Irish language in making medical appointments in the Free State. Dr. Tubridy (Galway), Dr. Ward (Monaghan), and Dr. White (Waterford) also took part in the discussion.

Lectures at Trinity College, Dublin.

The Mary Louisa Prentice Montgomery Lecture in Ophthalmology will be given this year by Mr. Louis E. J. Werner, M.B., D.O.M.S., in the School of Physic of Dublin University, on Thursday, April 25th, at 5 o'clock. His subject will be "The slit-lamp in clinical practice." A short course of lectures on anaesthetics will be given this term for medical students in their final year by Dr. T. P. C. Kirkpatrick, the University lecturer in anaesthetics. This course is intended to supplement the theoretical and practical instruction which is given at the clinical hospital. Arrangements have been completed for the holding of the usual three weeks' post-graduate course from September 16th to October 5th. As in former years, practitioners attending the course will be able to live in college chambers as far as possible.

Health Schemes in County Louth.

The Free State Local Government Department has sanctioned provision being made for the ophthalmic treatment of school children in County Louth. Under this scheme the Board has appointed Dr. Connolly to attend children who are recommended by the school nurses as needing treatment of the eyes. Hospital treatment also will be afforded, and a scheme for dental benefit is being arranged. It is proposed that dentists should visit the towns of Ardee, Drogheda, and Dundalk under the scheme, and that the children of poor parents should be attended free. The further use of ultra-violet ray treatment for patients who have left hospital is also being dealt with; and, on the recommendation of Dr. Musgrave, the Board has decided that in cases where the patients require further treatment, and are unable to pay the cost of rail or bus to the Ardee Hospital, the matron of that institution should be empowered to advance the necessary money. A feature of this scheme is that the hospital proper will be left available for more urgent cases.

England and Wales.

Proposed Clinic for Rheumatic Diseases at Brighton.

A MEETING of the medical practitioners in Brighton and Hove was held on April 3rd to discuss the need of a local clinic for the treatment of rheumatic diseases. Dr. George Morgan (chairman of the Brighton Division of the British Medical Association) was in the chair. Dr. J. Stanley Ellis, who opened the discussion, emphasized the growing interest in rheumatic disease as a cause of industrial inefficiency, and pointed out that the present efforts to reduce the increasing sick benefit expenditure and the appalling waste of time due to rheumatic disability were wholly inadequate. Early treatment was essential, since 80 per cent. of cases could be cured or much improved if efficiently treated within the first six months. The best way to secure early treatment was by local rheumatic treatment centres founded on the lines laid down by the Ministry of Health. The "arthritis unit" work could be done at the existing hospitals, and some in-patient accommodation be also provided locally; the electro- and hydrotherapeutic treatments needed specially designed institutions. Dr. Ellis said there was every inducement to start such a centre at Brighton with its many facilities. At present at the local hospitals only about 15 per cent. of patients were cured or returned to full work, whereas by a special clinic at least 40 per cent. ought to be cured and a further 30 per cent. enabled to do their ordinary duties for nine months to a year before requiring further treatment. Dr. M. B. Ray, honorary secretary of the National Campaign against Rheumatic Diseases, explained that this society was a development of the British Committee on Rheumatism, which was a purely provisional committee instituted nearly four years ago by the International Society of Medical Hydrology. At the wish and with the assistance of the latter body, the "Campaign" had now been launched as an independent organization, and it was intended to include in its membership representatives of all the various friendly and other societies and associations, both of employers and employees, who were especially interested in seeking to diminish the toll of sickness levied by the prevalence of these most distressing maladies. The campaign having been designed to support and co-ordinate measures against rheumatic diseases, its ideals could best be realized by educating medical opinion as to the necessity for early diagnosis and systematic treatment and by teaching the public to demand increased provision for treatment and research. The kind of treatment afforded in a centre or clinic comprised: the employment of heat, cold, and movement, in water vapour and hot air—locally and generally applied; manipulation and exercises, alone or in combination with heat, by the hand, or by douches or whirling water; radiation—as from heat, light, and the invisible rays; electricity—as constant current to resolve exudations and promote nutrition, as interrupted current to cause movement of muscle fibre, and as high-frequency current (diathermy) to raise the temperature of deep-seated parts. The clinic or centre should be in close association with a fully equipped hospital department, where patients could be sent for complete investigation and diagnosis. In such a hospital department or "arthritis unit," if a focus of infection had been discovered it would be removed, if deemed advisable. The bacteriological and biochemical investigation of each case sent there by the clinic would be undertaken before the patient was returned for treatment. Any necessary orthopaedic surgery would be provided at the "arthritis unit." In the first instance, all patients who desired to avail themselves of the treatment facilities would present themselves at the clinic or centre, which acted as a clearing house, the patients being directed to the form and place of treatment best suited to their needs. Dr. Ray thought that the establishment of a "rheumatic clinic" on these lines in Brighton would be a most valuable addition to the resources at present in existence for the combating of rheumatic diseases; there were facilities for the employment of sea water for therapeutic purposes. Dr. Duncan Forbes (medical officer of health, Brighton) emphasized the "arthritis unit" as being of the first importance, since by careful study of each patient by a team of medical experts, septic foci could be discovered in 70 per cent. of all cases. He hoped that the "arthritis unit" would be established at the Royal Sussex County Hospital, where all the necessary equipment for team work was already provided. He advised the establishment by the municipalities of a physical treatment centre which would compare favourably with those already at work in the various spas. Brighton would enhance its reputation as a health resort. The discussion was continued by Drs. Greenyer and Copeman, Sir Hubert Bond, and Dr. Parry, and it was resolved, finally:

> That this meeting of members of the medical profession in Brighton and Hove is of the opinion that facilities for the formation of a rheumatic clinic in Brighton would not only be of direct benefit to the residents in the County Borough and surrounding area, but would also be found to attract desirable visitors to the town.

It was agreed to send a deputation, consisting of Drs. Morgan, Broadbent, Parry, Edmonds, and Ellis, to the Brighton Town Council.

An Outbreak of Imported Small-pox.

The Chief Medical Officer of the Ministry of Health (Sir George Newman) reports that the facts of this outbreak, so far as ascertainable on April 12th, are as follows:

"The Anchor Line s.s. *Tuscania* left Bombay on March 14th after a stay at Bombay of a week or more. It is stated that the crew and passengers numbered some 900 to 1,000. Some 200 of the passengers left the liner at Marseilles on March 27th and travelled direct to London or elsewhere; the majority, however, remained on board the ship bound for Liverpool. At Marseilles an able-bodied seaman was landed on March 27th and died that day in hospital from small-pox. His condition had not been diagnosed on the ship, but was ascertained only when he arrived in hospital at Marseilles.

s far as our information goes, he had been ill from March 5th, and on the following day it appears that another member f the crew fell ill, though he was not landed at Marseilles, nor as he diagnosed as suffering from small-pox. He was removed o hospital on arrival at Liverpool on April 1st, and three or our 'contact' persons with this second patient were also moved to hospital. It should be added that when the hipping authorities learned at Marseilles that they had to deal ith small-pox infection on the *Tuscania* they obtained vaccine mph at Marseilles, and the ship's doctor undertook the nerous task of vaccinating, or revaccinating, the passengers nd crew. On arrival at Liverpool some 650 passengers disembarked, and information was sent by the Liverpool port uthorities to the districts to which they were stated to be roceeding. Several passengers subsequently proceeded on the *uscania* to Glasgow, where the crew were also disembarked. he authorities at Liverpool also informed the local authorities f the destination (as far as known) of the 200 persons who left he ship at Marseilles and travelled overland.

"On receipt of the information thus provided, the central nd local health departments in this country have proceeded in he ordinary way in regard to notification, isolation, disinfecon, etc., and are keeping as far as possible the various contact' persons under supervision. It is, however, obvious hat it is inevitable that if a number of persons, apparently ealthy at the time of disembarkation, leave a ship that has een infected with such a disease as small-pox, it is probable hat there will be a number of secondary cases of infection, rovided that such persons had not been adequately vaccinated efore their contact with the infection. There is, however, no use whatever for alarm in regard to this unfortunate incident. he average number of cases of small-pox of mild degree notified n England and Wales per week during the last three months as been about 250. To this prevalence of mild small-pox must ow be added a certain number of cases of small-pox of severe egree. Up to the present some 35 cases of this imported nfection have been notified in London and elsewhere, among hich persons there have been up to date five deaths.

"The means of the prevention of small-pox, whether of mild r severe degree, is the same—namely, vaccination. There can, f course, be no assurance as yet that the 'contact' persons ho were on board the *Tuscania* during its period of small-pox nfection will escape the disease, for they may have become nfected before being vaccinated on the ship. They may or ay not escape. But if they had been previously vaccinated or indeed were vaccinated on the ship) the *probability* is reatly in favour either of their entire escape from this malady r of their attack being less severe than if they had not been accinated at all. In any case, it must be added that an nvaccinated community is an unprotected community, as an nvaccinated person is an unprotected person."

Post-graduate Instruction in the University of Leeds.

A comprehensive series of post-graduate courses during May, June, and July has been arranged by the Faculty f Medicine of the University of Leeds. Commencing on May 1st, three series, each of six lectures, will be given on Wednesday afternoons. Dr. H. W. Davies will deal with cidosis, alkalosis, and ketosis, at the School of Medicine; Mr. A. Richardson will discuss emergency surgery, in the General Infirmary; and Professor W. H. Maxwell Telling will lecture on diseases of the ductless glands, also n the General Infirmary. The minimum number for ach class is ten. An intensive general course of clinical nstruction and lectures will begin on Monday, July 1st, t the General Infirmary and the School of Medicine, and will occupy the whole day. Professors Jamieson, McSwiney, McLeod, and Maxwell Telling will be in charge of their espective subjects, and other lecturers and demonstrators nclude Mr. Dobson, Dr. Veale, Mr. Oldfield, Dr. Cooper, Dr. Polson, and Dr. Anderson, who will deal with fevers. he fee for this course is five guineas, and the maximum umber that can be accepted is twenty-four, so that early pplication is necessary to ensure participation. Further nformation can be obtained from the Dean of the Faculty f Medicine, the School of Medicine, Thoresby Place, eeds.

Queen's Hospital, Birmingham.

The eighty-eighth yearly meeting of the Governors of he Queen's Hospital, Birmingham, was held on April 9th, hen the annual report and statement of accounts were dopted. Sir Charles Hyde, president of the hospital, ommented on the good progress made by the contributory cheme, and hoped that it would give valuable assistance n meeting a total deficiency in the hospital accounts of nearly £17,000. No fewer than ten beds had been endowed already by the efforts of students of the university. He called attention to the fact that there had been a considerable increase in the number of casualties treated last year. Mr. T. Oliver Lee, the honorary treasurer, announced that the extensions of the hospital had now been in use for two or three months, and that, consequently, in 1929 and subsequent years, there would be an increase in expenditure of between £12,000 and £14,000. Mr. A. W. Nuthall, F.R.C.S., spoke of the need for obtaining adequate supplies of radium for Birmingham as a whole. Dr. Purslow, chairman of the house committee, outlined the position of the Queen's Hospital under the contributory scheme and its associated organization, the Birmingham Hospital Saturday Fund. He said that the Queen's Hospital had abandoned the ticket system in 1875, and might claim, therefore, to be one of the pioneers in this respect. The hospital had, consequently, suffered through lack of subscriptions in comparison with hospitals that used tickets, and the contributory scheme had to meet this strain. He approved the scheme, however, and hoped that when the present difficulties were surmounted a financial grant might be obtainable which would be proportionate to the work carried on.

Correspondence.

THE LEUCOCYTES IN PERNICIOUS ANAEMIA.

SIR,—Dr. G. W. T. H. FLEMING, in his interesting paper published in your issue of April 6th, pleads for a closer study of the leucocyte in all patients suffering from pernicious anaemia. He refers more particularly to the deviation from the normal in the "polynuclear count," a change characterized by a shift to the right. This remarkable and significant variation in the blood is an essential characteristic of Addison's anaemia, and is one means of differentiating this disease from all other forms of anaemia, with the exception of sprue, and possibly that found in those infected with the *Dibothriocephalus latus*, and in lymphatic leukaemia.

The importance of such a finding is worthy of emphasis, since, up to the present, one fails to find any reference to it in the textbooks of medicine. Dr. Fleming gives the credit for the recognition of this characteristic change in the polynuclear count to Naegeli, 1919, and Arneth, 1920, and in so doing he has inadvertently overlooked the fact that this right-handed drift was first described by Dr. W. E. Cooke, in *The Arneth Count*, pages 18 and 19, published in 1914. It was there pointed out that, not only was this finding of diagnostic value, but that it necessitated a reconsideration of the fundamental etiology of this fascinating disease.—I am, etc.,

JOHN HAY.

Liverpool, April 15th.

SIR,—Dr. G. W. T. H. Fleming (April 6th, p. 638) has indeed done a most useful work in calling attention to the changes in the nuclear picture of the neutrophiles during the development of a remission of the disease. He seems to me, however, to have slighted the haemogram of Schilling more than is really justifiable. Schilling does not include all neutrophiles with *single, undivided nuclei* in one class (myelocytes and metamyelocytes), but differentiates them as myelocytes, young metamyelocytes, and metamyelocytes with band-like nuclei. Normally some 4 per cent. of the leucocytes are "band forms," whereas neither myelocytes nor young forms are found in health.

Dr. Fleming says that "the Schilling haemogram does not indicate any abnormality in pernicious anaemia apart from an inconstant lymphocytosis." My own findings do not quite bear out this statement; I have always found the percentage of band forms reduced, while a few young forms and even myelocytes are present. Surely the inclusion of all neutrophiles with unlobed nuclei in Class I of the polynuclear count must fail to give a clear insight into such a leftward shift as that shown by the haemogram.

It is, of course, essential that both the polynuclear count and the Schilling haemogram should be investigated in every case, but I can see no reason to suppose that either can justifiably be regarded as the more important.

May I also confirm Arneth's statement that there is a shift to the right in lymphatic leukaemia, although I do not know whether this is invariably so? At the same time there is almost always a general immaturity in Class I. of the polynuclear count. Similarly, in some, perhaps all, cases of Hodgkin's disease there is a shift both to the left and to the right, although this usually becomes less noticeable after *x*-ray treatment.—I am, etc.,

Maldon, Essex, April 6th. A. PINEY.

DEEP X RAYS AND THE CELLS OF THE BLOOD.

SIR,—Drs. Knott and Watt raise many important issues in their interesting preliminary note of their work on opsonic indices in radiated patients (March 23rd, p. 542). Much clinical work, however, showing the benefit of radiation in many acute and chronic septic conditions—work often confirmed fully by bactericidal blood tests—has shown that only in a very restricted sense is their statement to be accepted that "actively septic patients, leukaemic or otherwise, are not usually favourable subjects for irradiation."

Dr. Cave has pointed out (April 6th, p. 664) that, particularly in some acute skin infections, many good results have been obtained. But many other deeper acute and chronic infections have been successfully treated by radiotherapy. The report of Heidenhain and Fried (*Langenbeck's Arch. f. Chir.*, 1924, pp. 624–665) shows about a 75 per cent. rapid and excellent result in a series of 243 cases of such conditions as acute inflammatory glands of the neck and groin, acute mastitis, cellulitis of various regions, post-operative pneumonia, and parametritis; and these clinical results were confirmed by a series of bactericidal blood tests, which showed the beneficial effect of *x* rays on the patient as evidenced by the inhibited growth of stock and, more particularly, autogenous cultures.

Such bactericidal tests may be better than opsonic estimations for estimating the effect of radiation on septic conditions. But, apart from this point, the work of Heidenhain and Fried has shown clearly that radiation, to be successful in acute septic conditions, must not only be very closely watched twice daily in its effect, but must be very carefully applied *in doses about 20 per cent. of the mild skin dose*. Larger doses will not lead to the desired effect, and may even be dangerous.

The experience of many can confirm these results. It is not primarily a matter of the *quality* of the radiation used, as Dr. Cave suggests, but of the *quantity* absorbed, in comparison with some standard such as the skin dose, that is of importance to the result. For example, Berven, in his just published report on the "Treatment of tumours at Radiumhemmet" (*Acta Radiol.*, 1929, vol. x, p. 1), says that in ulcerated tumours "we have had great use of a resorbent Roentgen ray treatment prior to the radium treatment." A sixth to an eighth of a skin dose (high voltage) makes a great improvement in some days in the condition of cases of very septic cancer of the lip, and the subsequent radium treatment is facilitated.

I have had similar results in septic cancer cases; also with many non-malignant infections. If small but adequate doses are used, Dr. Knott and Dr. Watt's statement will be found to be far from a complete summary of the recently opened-up subject of the effect of radiation in acute and chronic infections.—I am, etc.,

London, W.1, April 12th. J. H. DOUGLAS WEBSTER.

DOSAGE OF THALLIUM ACETATE.

SIR,—Thallium acetate has been in use in the schools of the Brighton guardians for about eighteen months. The calculation for determining the right dose was rather complicated, involving the conversion of weights from the English system into the metric system and back again. On one occasion an overdose, fortunately not severe, occurred as the result of a mistake in the calculation. I then tried to find a simpler calculation. I found that *the weight of the child in pounds divided by 18 equals the dose of thallium in grains*. As an additional safeguard the weight of the child is put on the top of the prescription so that the dispenser can check the calculation. In view of the recent unfortunate disaster in London I thought perhaps that this simpler calculation might be useful to others, who may be alarmed at the risk of a mistake in estimating the dose.—I am, etc.,

Hove, Sussex, April 10th. H. J. MCCURRICH.

SIR,—There have been so many mistakes and discrepancies in the press reports on the inquest on the three boys who died from an overdose of thallium acetate that I would like to state the plain facts of the case. The strength of the solution should have been 7.8 mg. per fluid drachm, and was based on a prescription handed to the hospital dispenser about two years ago. The prescription was written in the hospital pharmacopoeia, and it has always been understood that the solution sent up from the dispensary would be that strength. Acting on this assumption, the correct volume of the medicine was measured out so that each child should receive a dose of 8.5 mg. per kilo of body weight. Unfortunately, the solution was not correct; a decimal point had been misplaced and each child received ten times too much—instead of 8.5 mg., 85 mg. per kilo were actually given.

A further point which was not made clear was that on analysis the solution from the small bottle "B" was only 5.6 times, and not 10 times, too strong. This is accounted for by the fact that after the children had received their medicine from the larger bottle "A," only about one ounce of the solution was left in the bottle, and on being returned to the dispensary it was emptied out into the smaller bottle "B," which already contained about one ounce of the solution left over from a previous occasion, and which was, of course, the correct strength.

One further remark I would like to make. In one paper I was reported to have admitted that one of the patients to whom I had administered the same medicine had afterwards gone off into a "trance." What I really said was that in all the series of cases we had treated only one reported having slight transient pains, and these did not occur until a week had elapsed after taking the medicine.—I am, etc.,

J. M. SPENCER SCOVELL, M.D., Ch.B.Ed.

London, W.1, April 15th.

THERAPEUTIC VALUE OF ULTRA-VIOLET LIGHT.

SIR,—In the introduction to the recently issued annual report of the Medical Research Council certain general comments with regard to light treatment are made. As these remarks are only in the general introduction it would be helpful to have an authoritative answer to the following question: Had the comments on light treatment been submitted for approval to the Medical Research Council's Committee on the Biological Actions of Light? If the answer is in the negative further observations are unnecessary.—I am, etc.,

London, W.1, April 12th. C. B. HEALD.

ESTIMATION OF HEPATIC EFFICIENCY.

SIR,—I hope you will kindly allow me to comment on the letter on the above subject in your issue of March 30th (p. 621), which referred to my report on Roch's test, recently published.

1. Your correspondent does not state how the results he quotes were interpreted as an answer to the question set.

2. No experiments seem to have been made on healthy subjects as controls for the results obtained with patients.

3. My experience with Roch's test on myself and other three healthy subjects gave positive results, and as similar results were obtained with patients having unhealthy livers this was regarded as proof that the elimination of salicylic acid in the urine is a normal result after its ingestion, whether the liver was diseased or healthy.

4. Your correspondent's positive results cannot therefore be accepted as proof that the liver's antitoxic function was disturbed in any single case, nor can much be inferred from the negative results, except that probably they arose from incomplete extraction of the salicylic acid, as was proved in my experiments.

These results need not be more fully analysed, but as a whole I consider they confirm the conclusion reached in my article—namely, that Roch's test is of no value in diagnosing disease of the liver.—I am, etc.,

London, E.1, April 12th. W. RALSTON.

THE CIRCULATION UNDER THE SPHYGMOMANOMETER CUFF.

SIR,—Dr. Harrington Sainsbury can be assured that the method used by me on the frog is the same in principle as that of the sphygmomanometer, and Mr. N. Pines confirms, as stated in his letter, for the eye viewed by the ophthalmoscope exactly what I see under the microscope in the case of the tongue or web of the frog. Dr. Sainsbury, I think, leaves out of account the difference of pressure in systole and diastole. As the compression is increased the flow becomes slower and pulsatile; next the flow only occurs during systole and ceases during diastole of the heart; finally the flow in the vessels stops and the blood is squeezed out, the direction of flow being reversed in the artery. Before the final cessation of the flow in systole the artery shuts up in diastole and opens at the height of systole enough to let a few corpuscles through.

When the pressure in the cuff of the sphygmomanometer is maintained, say, at 40 mm. of mercury, and rises to that pressure in the big veins below the cuff, it must be borne in mind that this pressure only pertains in the wider connexions between the arteries and veins. Owing to the increased resistance to flow as the pressure in the cuff rises, the circulation stops in capillaries where the frictional resistance is greater; the pressure is then not fully transmitted to these. If the middle portion of the frog's tongue be compressed by my apparatus the conditions are exactly equivalent to those pertaining when the cuff is applied to the arm.—I am, etc.,

National Institute for Medical Research, Hampstead, N.W., April 9th. LEONARD HILL.

THE ART OF SURGERY.

SIR,—The criticism of Mr. Souttar's claim for surgery as being essentially an art on the ground that it is not necessarily associated with any moral, spiritual, and, I might add, emotional experience, is, I think, right. The true aim of art is the expression of beauty in its physical, moral, spiritual, and emotional aspects. It may be difficult to define beauty, but its effects upon those who come within its reach are none the less genuinely felt. Mr. Souttar himself experienced them when engaged in contemplating the Venus of Milo. No one, however enthusiastic a surgeon he may be, is justified in claiming that witnessing an operation, in all its stages, however dexterously and beautifully performed, is capable of awakening in the spectator, or in the operator himself, feelings even remotely comparable with those produced by literature, music, painting, sculpture, and architecture. Surgery, moreover, is hardly a constructive activity, and as such it cannot be called an art in the sense in which those human achievements I have mentioned are arts. Plastic and orthopaedic surgery, for instance, which are practically the only constructive portions of a surgeon's work, however much they may and do serve a useful purpose, cannot by any stretch of imagination be called beautiful in their results, except in so far as those results appeal to our perverted sense of true beauty in its application to surgical practice. No one denies that art forms part of surgery, but its scope is limited; all great art is essentially creative, which surgery is not, and never can be. It is not through any fault of Mr. Souttar's that his achievements, high as they are, cannot come up to the level reached by workers in other realms of art. The reason lies solely in the limited artistic values of the materials at his disposal, whereby the fullest expression of his obviously very artistic nature is unavoidably and irretrievably curtailed.—I am, etc.,

Greenhithe, April 7th. D. W. STANDLEY.

THE TREATMENT OF ACUTE OTITIS AT PUBLIC SCHOOLS.

SIR,—There is a circumstantial story going the round just now, which I will repeat for whatever it may be worth, because it points the moral of something I have to say later. It is said that an otologist was recently summoned to a public school and found there four boys with five acute suppurating mastoid antra between them; he operated at once upon all four. All the patients had had acute otitis media; on none of them had a paracentesis tympani been performed.

Now what I can vouch for. Last term my eldest son developed scarlet fever at his public school. (Incidentally his mother found out he was ill at a half-term visit, when he had already had symptoms for thirty-six hours—naturally, an epidemic followed). The next day I visited him and learnt that he had left-sided earache. I saw the school doctor and urged the importance of paracentesis. He agreed enthusiastically and promised to have it done if the drum should bulge. I went down a week later, and discovered for the first time that the drum had been allowed to rupture two days after my first visit. I offered no reproaches: I wish now that I had made myself unpleasant, for, soon after, a right otitis developed, and that, too, was allowed to take its own time in rupturing through the drum. An acute mastoiditis supervened necessitating a midnight operation and, of course, a prolonged convalescence.

I am moved to ask two special branches of the profession certain questions. I ask the otologists, Is early paracentesis the proper treatment for acute suppurating otitis media? Does it lead to speedier recovery, less chance of deafness, greatly diminished liability to acute mastoiditis? If the answers are affirmative, I ask the Medical Officers of Schools Association what they have to say on these topics, which seem to me to be of some importance to them.

I have been in private practice for twenty-two years, and have never yet met with an acute mastoid case; largely luck, no doubt, but partly, I think, because I believe in the surgical drainage of abscesses behind the tympanum. As I am only concerned to protect boys and girls in the future, I take leave to sign myself only by my degree of—

April 15th. M.D.

THE ORGANIZATION OF A MATERNITY SERVICE.

SIR,—With reference to Dr. Farquhar Murray's interesting article in the *Journal* for April 13th (p. 691), I would like to mention that the Bristol Health Committee has instituted a scheme whereby any medical practitioner in Bristol can secure the services of a member of a panel of obstetric specialists whom he may wish to call in to a case of difficult labour. The Health Committee undertakes to be responsible for payment if the patient cannot afford the necessary fee. This scheme, which has only been in working for a few months, has shown results which promise to be of great value. May I state that I am in full agreement with Dr. Farquhar Murray's views in regard to handywomen.—I am, etc.,

R. A. ASKINS, M.D.,
Bristol, April 16th. Medical Officer of Health.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

WHEN the House of Commons reassembled, on April 15th, after the Easter recess, Mr. CHURCHILL introduced the Budget for 1929–30. He drew attention to a decrease in the excise duties on beer and the customs duties on wine, and asserted that these resulted from a change in the national habits, which was an embarrassment to the Exchequer, but not a misfortune to the nation. The returns from the spirit duties had only been kept up by the exceptionally cold weather in the early part of this year. He proposed the total and final abolition of the tea duty from April 22nd, including the duty on tea grown outside the Empire. He proposed no remission of the duties on cocoa and coffee in this Budget, and no changes in the taxes on sugar and petrol, nor in the income tax, supertax, and death duties. Slight adjustments were proposed in the licence duties on brewers, distillers, and tobacco manufacturers, but no increase is to be charged in the present duties where the output of spirits on which the duty is calculated is for methylation or use in arts or manufacture. It is proposed to allow certain holders of off-licences to sell spirits by the half-bottle. Reductions are proposed in the licences for some classes of motor-propelled goods vehicles, and some motor cycles, but not on passenger motor cars.

Mr. CHURCHILL announced, on March 16th, that the present Parliament would in any event end before Whitsuntide. The

general anticipation is that a prorogation about May 8th will be immediately followed by a dissolution and by the general election campaign.

Lord Moynihan took his seat in the House of Lords on April 17th. He was introduced by Lord Dawson of Penn and Lord Illingworth.

Radium.

Dr. VERNON DAVIES, on April 16th, asked the Prime Minister what action the Government proposed to take on the report of the subcommittee of the Committee of Civil Research on Radium.

Mr. Churchill's Statement.

Mr. CHURCHILL, who replied, said: In view of the importance of the matter and the public interest attracted by it, the Government arranged for the immediate publication of the report. It will be seen that the report deals with the national requirements for radium in medical treatment, in the Fighting Services, and for the purposes of physical research; and with the possibilities of developing new sources of supply. Further, in a full statement as to the use of radium in medical treatment, the subcommittee has indicated that a great volume of avoidable distress and suffering persists simply because the radium required for the treatment of cancer is not available; and that the acquisition of further supplies should encourage the wider development of the highest skill in its use and the allocation of more hospital beds to the treatment of suitable cases. The subcommittee expresses the opinion that in order to meet the requirements of England and Wales, and of Scotland, 20 grams of radium, in addition to the stocks already available or likely to be available shortly, for general medical use, should be acquired within a specified period—namely, before the end of 1930.

The subcommittee recommends that the necessary sum, estimated at £200,000, should be raised by a public appeal, to which the Government should contribute pound for pound within that maximum sum. The subcommittee also proposes the setting up of an organization consisting, first, of a body to hold the funds and purchase and hold the radium, and, secondly, of a body to distribute the radium and secure its full use in the manner best adapted to further the advancement of knowledge and the treatment of the sick. As regards the recommendations of the subcommittee on the subject of the organization, these have been accepted in principle by the Government, but the precise form of the organization will remain open to further discussion. The Government has accepted the financial recommendation of the subcommittee, and will be prepared to contribute from public funds, up to a maximum of £100,000, to the extent of £1 for every £1 of private subscription for the purchase of additional radium. The Government confidently expects that there will be no difficulty in raising, in a very short space of time, the funds necessary to provide this invaluable addition to the national resources for battling with one of the most formidable maladies known to us.

Mr. RAMSAY MACDONALD asked if the Government had considered the effect of this announcement on the price of radium, and if it proposed to take any steps to safeguard itself in that matter. Mr. CHURCHILL: I understand that all that is dealt with in the committee's report. The House is entitled to the report and therefore publicity is unavoidable, but I do not apprehend any serious evil consequences.

Commander BELLAIRS asked if the report dealt with the international aspects of radium, and if it made any recommendation concerning the matter before the League of Nations, especially with regard to the Belgian monopoly. Mr. CHURCHILL said that he must confess that, like Commander Bellairs, he was looking forward to studying the report.

Lieut.-Commander KENWORTHY asked if the right hon. gentleman was aware that every time the Government had gone into the market to purchase radium the price had been raised against it, and if he would consider the suggestion of Commander Bellairs and advise the Foreign Office to examine into the matter of international action. Mr. CHURCHILL said that he understood, though he did not speak with first-hand knowledge, that this matter was fully discussed in the report. Replying to Dr. VERNON DAVIES, who asked if there would be an opportunity to discuss the report, Mr. CHURCHILL said that it did not seem to him that the House was going to have much opportunity for further discussion.

Sir R. THOMAS asked if the report dealt with the potential supply of radium in Australia. Mr. CHURCHILL: That is covered by the statement that I have not yet been able to study the report. Mr. R. MORRISON asked if it would not be necessary for the Government to have a supplementary estimate. Mr. CHURCHILL replied that whatever was right and necessary would certainly be done. Mr. W. THORNE asked what was the approximate cost of an ounce of radium. Mr. CHURCHILL replied that he was sorry that he did not happen to have that information. Mr. THORNE: Is the right hon. gentleman aware that the cost is about £400,000 per ounce?

On April 15th Dr. VERNON DAVIES asked a question on the same subject. Sir KINGSLEY WOOD said that the report of the subcommittee of the Committee of Civil Research would be published. The question whether the report should be brought before the League of Nations would be considered.

Small-pox.

Dr. FREMANTLE asked, on April 15th, the number of passengers landed from the s.s. *Tuscania* which recently arrived at Liverpool from Bombay; whether passengers and crew were under observation; what number of cases of small-pox had occurred among them; the number and vaccination history of the cases that had died; and whether any cases of small-pox had been notified from contacts with passengers and crew. In reply, Sir KINGSLEY WOOD referred Dr. Fremantle to the statement on the case which had been issued by the Ministry of Health and is published at page 742 this week. At present the Minister of Health was not in a position to make any further statement.

Mr. T. JOHNSTON asked the Secretary for Scotland whether he was aware that a member of the crew of the *Tuscania* was discharged at Marseilles; whether subsequently a wireless message was received from Marseilles intimating that the man had died of small-pox; whether on arrival at Liverpool the other members of the crew were taken to hospital for small-pox; whether on arrival at Glasgow, and before fumigation or disinfection of the ship, an engineer, along with twenty-three cases of chickens and seven barrels of ducks, was transferred to the s.s. *Caledonia*, which sailed for New York on April 7th; whether the Transport Workers' Union informed the ports' medical authorities of the transfer of the engineer and the foodstuffs from the infected ship prior to the sailing of the *Caledonia*; why nothing was done to prohibit this proceeding; if forty bags of flour had since been transferred from the infected vessel to the s.s. *California*, and whether the Secretary of State could assure the House that all proper steps were being taken to prevent a spread of the infection. Sir J. GILMOUR, in reply, said that he had been unable to obtain information on the detailed matters referred to. He was making inquiries and would communicate the result to Mr. Johnston after these had been completed. He was satisfied that all reasonable steps were being taken by the competent authorities in Scotland to deal with the position and to protect the interests of the public.

Universities and Colleges.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

THE annual dinner of the Fellows of University College, London, will be held at the College on Tuesday, April 30th, at 7.15 for 7.30 p.m., in commemoration of the laying of the first stone of the College buildings by H.R.H. the Duke of Sussex on April 30th, 1827. Professor F. W. Oliver, M.A., D.Sc., F.R.S., elected a Fellow in 1886, will preside.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY Council meeting was held on April 11th, when the President, Lord Moynihan, was in the chair.

The secretary reported the death of Sir Anthony Alfred Bowlby, Bt., past President and past Member of the Council. The following vote of condolence was passed:

> The Council hereby express their deep regret at the death of Sir Anthony Bowlby, and their very sincere sympathy with Lady Bowlby and the members of her family in their bereavement. The Council also desire to express their grateful sense of the many services rendered to the College by Sir Anthony Bowlby during the twenty-four years he served as a Member of the Council, and especially to record their appreciative recognition of the distinction and ability with which he fulfilled the duties of President during his three years of office. The Council feel that the College has lost one of its most illustrious Fellows, who will long be remembered for his eminence as a teacher of clinical surgery, his conspicuous services during the South African and Great Wars, and for the zeal and ability which he brought to bear in the discharge of many duties undertaken by him on behalf of the State and the medical profession.

The honorary Gold Medal of the College was awarded to Sir George Makins, G.C.M.G., C.B., LL.D., in recognition of his valuable services to the College, more especially in arranging and describing the series of drawings in the Army Medical War Collection.

Sir D'Arcy Power was appointed honorary Librarian of the College in recognition of his services in re-editing Plarr's *Lives of the Fellows* and of his distinguished position as a bibliographer.

The Jacksonian Prize for 1928 was not awarded. The subject for the Jacksonian Prize for the year 1930 is "The pathology of ovarian cysts and its bearing on their treatment."

The vacancy in the Court of Examiners occasioned by the expiration of Sir Cuthbert Wallace's term of office on May 8th next will be filled up at the next meeting of the Council.

The following Members of twenty years' standing were elected to the Fellowship: Comyns Berkeley, M.D., M.Chir., obstetric and gynaecological surgeon to the Middlesex Hospital; William Blair Bell, M.D., B.S., obstetric and gynaecological surgeon to Liverpool Royal Infirmary.

On the recommendation of the Museum Committee it was decided to devote Lord Beaverbrook's grant of £1,000 to tissue culture research.

Obituary.

SIR ANTHONY ALFRED BOWLBY, BT., K.C.B., K.C.M.G., K.C.V.O.,

Honorary Surgeon to the King; Past-President of the Royal College of Surgeons of England; Consulting Surgeon to St. Bartholomew's Hospital.

As briefly announced in our last issue, Sir Anthony Bowlby, the eminent surgeon, died on April 7th at Stoney Cross, in the New Forest, at the age of 73, after a short illness.

Anthony Alfred Bowlby, third son of Thomas William Bowlby, was born on May 10th, 1855. His father first practised as a solicitor in London, and later was special correspondent of the *Times* at Berlin and in China, where he died in 1860 as the result of ill treatment from the Chinese, who took him prisoner after the capture of Tientsin. From Durham School Anthony Bowlby went to study medicine at St. Bartholomew's Hospital, and distinguished himself both at work and at games. He became M.R.C.S. and L.S.A. in 1879, and after winning the Brackenbury scholarship in surgery and serving as house-surgeon to Sir Thomas Smith, was admitted F.R.C.S. in 1881. His next appointment at St. Bartholomew's was that of curator of the museum, where he spent laborious days in completing the catalogue of pathological and anatomical specimens begun many years before by Sir James Paget. This early work in the museum and the post-*mortem* room laid the foundations for Bowlby's *Surgical Pathology and Morbid Anatomy*, a textbook highly popular with students, which first appeared in 1887 and reached its seventh edition in 1920, with Sir Frederick Andrewes as joint author. In 1882 Bowlby was awarded the Jacksonian prize of the Royal College of Surgeons for his dissertation on "Wounds and other injuries of nerves, their symptoms, pathology, and treatment"; in 1886 he won the Astley Cooper triennial prize for his essay on "The surgical treatment of diseases and injuries of nerves"; and in the following year he was Hunterian Professor. In 1891, after serving for seven years as surgical registrar, he was elected assistant surgeon to St. Bartholomew's, and became full surgeon in 1903. Bowlby was an excellent teacher with a clear crisp direct style, and his clinical lectures on surgery, no less than his informal talks to dressers in the wards, were valued by generations of students. On his retirement from the post of senior surgeon and his election to the consulting staff in 1920, he was presented by his colleagues and pupils with a portrait of himself in recognition of his services to the hospital and medical school and of the appreciation felt by all Bart's men for his distinguished work for military surgery. He was also for many years surgeon to the Alexandra Hospital for Hip Disease in Queen Square, Bloomsbury, and to the Foundling Hospital.

SIR ANTHONY BOWLBY, BT.

Soon after the beginning of the South African war Bowlby went out with the Portland Hospital as senior surgeon in charge, and threw himself with characteristic zeal and vigour into the administrative and surgical work of that war hospital, which was first established at Rondebosch near Capetown, and later moved up to Bloemfontein. For these services he was awarded the C.M.G. Some of his South African experiences were printed in these columns; and he gave a fuller account of them in a book entitled *A Civilian War Hospital*. After holding for some years the post of surgeon to King Edward's Household, he was appointed Surgeon in Ordinary to King George on his accession to the throne, and received the honour of knighthood in 1911. When the British Red Cross Society was founded in 1905 Bowlby was one of the three surgeons chosen by Queen Alexandra to act on the council; thenceforward until his death he was a greatly valued member of its executive committee, his knowledge of military surgery and administration enabling him to forward the society's work in many directions.

The outbreak of war in August, 1914, gave him further and wider opportunities for serving his country. He was soon at G.H.Q. in France, and was made advisory consulting surgeon to the B.E.F., with the temporary rank of major-general A.M.S. No plan formed in the early days of the war was more fruitful of good than that which led to the appointment of distinguished members of the staffs of civilian hospitals to be consulting physicians and surgeons with the armies oversea, and later for each military command in the United Kingdom. Passing constantly to and fro among the medical units they carried the experiences of one to the other, so that they were able to advise the chief administrative medical officers as to the means that should be taken to prevent disease or anticipate infection, and to afford opportunities for efficient treatment at the earliest possible moment. Experiences were collected and compared, meetings of the medical officers of an army were held for discussion, and the consultants of all the armies met together, until finally opinion on some problem or set of problems could be crystallized into a memorandum which was issued from G.H.Q. for information and guidance to the medical officers of each army. In all this Sir Anthony Bowlby took a leading part, his personality and habit of mind suiting him exactly for the work that had to be done. He was a familiar and welcome figure at every casualty clearing station, and often visited the field ambulances. In the words of a Territorial medical officer, "There was no more truly respected man than he at the Front. His excellent advice was always at our service, he never failed to be encouraging, and though his position in the medical service was so senior he often constituted himself a humble assistant of the junior." He was five times mentioned in dispatches, created K.C.M.G. in 1915, K.C.V.O. in 1916, C.B. in 1918, and K.C.B. in 1919. The Government of the United States awarded him the American Distinguished Service Medal.

In 1915 Sir Anthony Bowlby gave the Bradshaw Lecture before the Royal College of Surgeons, on "Wounds in war,"

and in 1919 the Hunterian Oration, on "British military surgery in the time of Hunter and in the great war." In the following year he was elected President of the College in succession to Sir George Makins, his colleague in France throughout the war, and held office until 1923, when he was created a baronet. Among the other civilian distinctions that fell to his lot were the honorary fellowship of the American College of Surgeons, and the honorary degree of D.C.L. of the University of Durham. He was for very many years a member of the British Medical Association, and often showed his friendship for the Association and its *Journal*. At the Annual Meeting in 1891 at Bournemouth he was secretary of the Section of Surgery, and at the London Meeting in 1895 he was vice-president of the Section of Pathology and Bacteriology. In the arrangements for the special clinical and scientific meeting held by the Association in London after the armistice he took an active part, and presided over the discussion on wound shock. He was for some time a member of the Metropolitan Counties Branch Council, and in 1922–23 was a valued member of the Arrangements Committee at headquarters.

The funeral service, on April 10th, was held very appropriately in the Church of St. Bartholomew-the-Great, West Smithfield, and the large congregation included leading representatives of the public institutions and bodies with which he had been associated, and many former colleagues and pupils.

We are indebted to Sir WILMOT HERRINGHAM for the following appreciation:

Bowlby and I were of almost exactly the same age—he was about three weeks the younger—but he was my senior at St. Bartholomew's, since I had gone to Oxford before coming up to town. We rose, therefore, through the various grades more or less together. When I was demonstrator he was surgical registrar, and when I was medical registrar he was already assistant surgeon. About 1895 I became assistant physician (the "physician in reversion" of Harvey's time), and I then joined him as joint treasurer of the school, and began to take an active part in school politics. The school was in low water at that time, and the yearly income was very much lower than it had been ten or twenty years before. But a younger generation was coming on, and we made it our policy first to improve the teaching in every possible way, and secondly, to make the junior appointments better than they had been, even though this should involve some loss to ourselves as seniors. Bowlby himself had long pursued the same aims, and had gained a great reputation as a teacher among the students. As he rose to the higher ranks he held steadily to the same policy, and was one of the most unselfish and devoted servants that the school has ever had.

Two great changes took place in our time. The first was the abolition of the share system, and the payment by definite rates for the work done. This was the consequence and the condition of a grant from Government, given, I think, at that time by the Board of Education. The second, which came later, was the closer connexion of the school with the University. To both of these changes Bowlby lent an active support. The second was a remarkable instance of his sagacity, for he had no connexion with the University, which at that time was highly unpopular in the schools. He foresaw that it would raise the academic status of the school, and that was enough.

In the middle of this movement he and I went out to the war. There he was attached to G.H.Q. and had, as his main duty, the supervision of the clearing stations. They were a formation organized since the Boer war, and as yet untried in practice. No one knew exactly what their task would be. The stationary conditions of the war in France settled the question for that front. The dreadful nature of the injuries required immediate surgical aid, and the clearing stations became first-class hospitals, where surgery of the most advanced and daring kind was made possible first by provision of the necessary equipment, and later by the drafting of every available surgeon, sometimes, I am afraid, even to the detriment of the base, to the seat of fighting at the time. The clearing stations never, of course, took the place of the base. They did, however, the work necessary at the moment, the immediate repair of injuries which must otherwise have proved fatal before the patient could reach the base. It is not more than the truth to say that in this development Bowlby was the guiding spirit.

Perhaps I may be allowed a few words of personal tribute. Bowlby and I worked together for forty years. During the whole of that time I will not say that we never differed, but we never differed on serious points, and our friendship never was interrupted for a moment. We lived together in France for four years and a half, and I am sure that during the whole of that time we never said a cross word to one another. I remember the only time that I ever saw Bowlby really depressed. It was when the 5th Army were being forced back in 1918. The news grew worse and worse, and at last one Monday we received orders to prepare to fall back. We were then quartered at Hesdin. That night we sat over the fire and I think we were both very nearly crying. The next morning we were told to await further orders, and on Wednesday we were ordered to stay where we were.

Bowlby was the best collector of news I ever knew. Every night he brought back stories of the fights, statistics of losses, and the gossip of the front. Our companionship at the front was one of the most interesting episodes of my life.

Sir FREDERICK ANDREWES writes:

Sir Anthony Bowlby was, first and foremost, a surgeon, but he was also, as his writings testify, a good pathologist. It might be said that with him surgery and pathology were one subject, and that he was a good surgeon because he was a good pathologist. His knowledge of pathology, moreover, was not mere book knowledge, but was the fruit of his own observation and research. His opportunities had been great, for he had been trained in the school of surgical pathology at St. Bartholomew's Hospital started by Stanley and carried on by Paget and Savory, and in place of the dissecting rooms it was the museum and the post-mortem table which led him to the hospital staff. As curator of the museum he had to examine the material from the operating theatres, and thus laid the foundation of his accurate knowledge of morbid histology. On relinquishing his post in the museum he became surgical registrar (there was but one in those days), and, as such, he performed all the surgical post-mortems at the hospital. It was of these exceptional opportunities that Bowlby took full advantage, and it is not too much to say that upon these he built much of his surgical success.

While others knew him chiefly as a surgeon, I was associated with him mainly on the pathological side, and this association lasted for more than forty years. I was a student at St. Bartholomew's when Bowlby was surgical registrar, and I can well recall the benefit I derived from his teaching. He was a born teacher, and no trouble was too great for him to take where the welfare of the students was concerned. It was he, I believe, who instituted the weekly demonstrations on the surgical post-mortem specimens which had been obtained during the preceding week, and it was he, in conjunction with the late Sir Norman Moore, then medical registrar, who instituted the systematic teaching of morbid histology in the hospital. The class was held in the physiological laboratory every Friday at 4.15 p.m., and it so continued, though afterwards in other hands, for nearly forty years. Four students, of whom I was one for several sessions, were appointed as "cutters." We cut with an old-fashioned freezing microtome, stained the sections, and gave them out to the students in clove oil. We cut a great deal more material than was ever given out to the class, and we learned proportionally more. Bowlby would come to go over our sections with us once a week, apart from the class teaching, and I well remember how highly we valued these demonstrations. It was about this time that Bowlby produced his little book on *Surgical Pathology*, characteristically dedicated to the students of St. Bartholomew's Hospital. The feature in this work upon which he always laid special stress was its "clinical" character. It taught the student just the sort of pathology which helped him in his surgical work; it was pathology and surgery in one, and that was

perhaps the reason for the book's success, for it has had a much longer life than most works of the sort. Although Bowlby had to seek the help of coadjutors in the later editions, he always strove to maintain the clinical character of the book unaltered. It was largely owing to Bowlby's prescience that Kanthack was appointed as whole-time pathologist at St. Bartholomew's in 1893; he it was who proposed the change and carried it in the face of a good deal of opposition; it was a new departure, for no hospital in London then had a pathological specialist on its staff.

As a pathologist Bowlby, trained as he had been in the old school, was naturally a morbid anatomist and histologist, but during his career as a surgeon he witnessed the steady development of clinical pathology and bacteriology, witnessed it with his eyes wide open, and was ready to take full clinical advantage of all that it had to offer. For he never became a fossil, and those who came into contact with him during the last and greatest work of his life, during the war, saw clearly how greatly his success in organizing the treatment of the wounded was based on his readiness to accept new pathological ideas.

SIR CUTHBERT WALLACE writes:

I first remember Bowlby at a time when I was a commencing student and he had his feet on the ladder up which he climbed so far. I remember him in his home at Maida Vale, and also as a keen and energetic climber of the Swiss mountains in company with his friend Stedman. He seemed a long way above myself, and I often turned to him for advice. In the autumn of 1899 he asked me to join the staff of the Portland Hospital, and with him I sailed from Liverpool in the *Majestic*. We worked together, at first at Rondebosch and later at Bloemfontein, until the hospital was broken up in July, 1900. It was during this time that I first became aware of his power of dealing with difficult situations and smoothing out differences. It is remarkable that he had this faculty, as he was a man of very definite opinions, whether they were right or wrong. It was this downright attitude of mind that made him a successful teacher. During the years that followed the Boer war our friendship continued, and I was often a guest in his home in Manchester Square.

In May, 1915, I was handed over to him at St. Omer to be introduced to my new duties. He remained at General Headquarters, and, in addition, looked after the 2nd Army, while I was attached to the 1st Army. There then began a period of close companionship and consultation which lasted till the end of the war. With the establishment of additional armies new consultants were appointed, and Bowlby became a superconsultant and general adviser at the front. His work entailed a life spent in a motor car, traversing great distances, over roads which were not first-rate. It was a matter of surprise and admiration how he stood up to the strain in all weathers and in all seasons. He was always cheerful, always welcome, and always full of news. He was constantly on the look out to circulate knowledge, and to think out and suggest administrative adjustments. Often after a strenuous day he would sit down and indite memoranda and reports. The wounded man owed him a lot.

Bowlby had a conservative turn of mind. On the other hand, if he was once convinced that any project was good he would push it with all his might. He was a good man to have on your side, if you could persuade him to join you. Another striking attribute was his power of extracting the essence of a subject and his ability to disregard inessentials. He was a counsellor who almost invariably strove for peace. He was a good friend, and many will miss him.

Lieutenant-General Sir ARTHUR SLOGGETT, who was Director-General A.M.S. from 1914 to 1918, sends the following tribute:

I first met Bowlby when he was in charge of the Portland Hospital during the South African war. There he did very good work indeed, and from that time began his connexion with the British Red Cross Society. When the European war broke out I was extremely anxious to obtain his services as consulting surgeon in France. My desires were fulfilled; I made him consulting surgeon for the whole of the front line, and my friend Sir George Makins was consulting surgeon for the whole of the lines of communication. Bowlby was of the very greatest help to me throughout the war. When I first went to France the relations between the R.A.M.C. and the civilian surgeons in the Red Cross organization were by no means free from friction. I met the situation by giving all the medical officers rank, so that they became, as it were, one family. The possibilities of quarrel thus disappeared, the whole service worked together as one, and it was, to use Bowlby's own frequent words, "a very happy show." In securing this most essential condition for the efficiency of the service at the front I owed much to Bowlby himself. Behind his somewhat gruff exterior he had admirable qualities of tact and a great wisdom in dealing with men. At our headquarters, which were first at St. Omer and afterwards at the village of Hesdin, in the Pas-de-Calais, we worked together in the most intimate way, and in all our association, official and personal, then and afterwards, in times of great exigency and in times of waiting, we never developed any disagreement.

Bowlby's surgical skill was, of course, of a very high order. He was immensely painstaking in everything he did, and he possessed enormous vitality and physical strength. He could take on a vast amount of work and carry it through without visible signs of fatigue. He often amazed me by his untiring energy. I was always an "early bird" myself, but here was Bowlby very often up and "on the warpath" in front of me, going his rounds of inspection. One interest we had in common was a love of cricket. I have been a member of the M.C.C. for the best part of half a century, and one of my pleasures was to get seats for Bowlby at Lord's on the occasion of the big matches. I do not know that he had ever played very much cricket himself, but he had a keen appreciation of the game. He played the game of life in the same clean way. One other personal association which I treasure was his armistice dinners. It was his custom every year since the war to give a dinner on November 11th to all the leading surgeons who were at the front with him. I never missed attending one of those gatherings. Alas, that there should be no more of them!

I may add that the King had a great regard for his honorary surgeon. In his visits to the front His Majesty would inquire after Bowlby with a turn of speech which showed his affection for the man. That was a feeling, indeed, which any who really knew him must have shared. He was a man's man, with a chest of iron and a heart of gold.

Major-General Sir S. G. GUISE-MOORES writes:

It was in the South African war of 1900–2, when Sir Anthony Bowlby had surgical charge of the Portland Hospital, that I first came across him. Then not again until after a long interval—in 1915 during the great war. He was at the time the advisory consulting surgeon to the British Expeditionary Force in France. Both he and Sir Wilmot Herringham came as consultants to the Belgian Enteric Hospital for civilians at Malassise, near St. Omer, of which I was the officer commanding. Sir Wilmot, as consulting physician to the British Expeditionary Force, visited it regularly, and brought Sir Anthony Bowlby with him as occasion demanded, for at times there were important surgical cases on our hands requiring an expert opinion. But it was when director of medical services of the 2nd Army that, apart from his reputation as a surgeon, I learnt to value and appreciate the man himself, his qualities of mind and heart, and his strong and virile personality. He had been known to follow, by his presence, wounded from the field ambulance, advance and main dressing stations, to the clearing stations, and, when the spirit prompted him, to go right up to the regimental aid posts. At the clearing stations he was a frequent visitor, and soon became the prime mover in regularizing improvements in surgical procedure and technique, in relation to the treatment of wounds at the front. He was also the promoter of harmonious co-operation between the military and civilian elements, which contributed so much to the efficiency of the growing number of the elaborate clearing stations that lay behind the lines. We always looked

forward to his timely visits to D.M.S. headquarters; for he was the most sensible of optimists, and the most loyal of colleagues; a breezy wave of confidence seemed to usher him into its portals. His decisions were formed on sound reasoning, but if by any chance he afterwards found that error had crept in, he was the first to recognize and acknowledge it.

He was on the staff of Osborne House, and of late years it has been my good fortune to welcome him on his week-end visits. This fuller intimacy enabled one to recognize the many-sided facets to his character, his singleness of purpose, and his set duty, to help others, particularly the ex-soldier, in surmounting the uphills of life. The thought, time, and labour he gave for the betterment of the fighting man in the war will ever be gratefully remembered. It is possible that Sir Anthony counted the years of his army service in South Africa and France as among the happiest in a career full of honour. There is no doubt that from the start he had implanted in his being the seeds of an administrator, and that these fructified in full measure in an atmosphere so suited to his abilities and so congenial to his temperament.

[The photograph of Sir Anthony Bowlby reproduced at page 747 is by Elliott and Fry, London.]

SAMUEL HERBERT BURTON, M.B., F.R.C.S.,

Consulting Surgeon to the Norfolk and Norwich Hospital, and the Norfolk and Norwich Eye Infirmary.

WE regret to announce the death of Mr. S. H. Burton in his seventy-sixth year, at his residence in Norwich, on March 30th.

Samuel Herbert Burton received his medical education at University College Hospital, graduating M.B., B.S.Lond., with honours in medicine and midwifery in 1876, in which year also he obtained the diploma M.R.C.S.; in 1881 he became F.R.C.S. by examination. After holding the posts of house-surgeon, house-physician, surgical registrar, demonstrator of pathology, and assistant in the obstetrical and ophthalmological departments at University College Hospital, he was appointed house-surgeon to the Norfolk and Norwich Hospital in 1878. Ten years later he became assistant surgeon, in 1898 full surgeon, and in 1919 consulting surgeon. His administrative ability was recognized by his election as chairman of the Board of Management in 1923. In addition to these appointments he was consulting surgeon to the Jenny Lind Hospital for Children, and surgeon to the Eye Infirmary; until his death he was chairman of the Infirmary committee.

Mr. Burton was a member of the British Medical Association for many years; he was vice-president of the Section of Surgery at the annual meeting in 1900 at Ipswich, and in 1909 held office as chairman of the Norwich Division. He was a justice of the peace for Norwich. He was in active practice until within a short time of his death, and had a distinguished reputation as an operator and accoucheur. In February he had a severe attack of influenza and pneumonia, but recovered sufficiently to resume work. A little later, however, following a relapse, he died after a short illness. He is survived by his widow, two sons, and two daughters.

A colleague writes: It is a high tribute to his professional success to say that Burton was not only a first-class general practitioner but also a hospital surgeon of exceptional ability. The combination is rare in these days of specialism, and those who maintain that every consultant should have had experience of general practice would find in Burton's career a strong argument in support of that contention. The thorough grounding in the science of surgery which his early appointments gave him enabled him to take full advantage of the large and varied clinical experience which his hospital and private practice afforded. But he owed as much to his personal qualities as he did to his training. Careful and painstaking in forming an opinion, firm in holding it, temperate in expressing it, always ready to listen to the views of others, an indefatigable worker — it is little wonder that his influence with his colleagues and the hold he had over his patients were great, and that the members of the hospital boards on which he served always listened to him with attention and confidence. Few men have seen more of the frailties of mankind; few have gained a deeper knowledge of human nature; yet he was never cynical, and he never forgot that his patient was first of all a human being. The Norfolk and Norwich Hospital owes him a great debt. Its interests to him were paramount, and he served it well and skilfully, both as a surgeon and as an administrator. It can be truthfully said of him that he was one of those who "were honoured in their generation."

The sudden death of Dr. WILLIAM LOUIS BYHAM, on March 19th, at his residence in Sunbury-on-Thames, caused a painful shock to his many friends. He had been actively engaged in professional duties during the day, but about 11 p.m. he suddenly collapsed and died. Dr. Byham joined St. Thomas's Hospital as a medical student in 1879, and obtained the diplomas L.R.C.P., L.R.C.S.Ed., L.R.F.P.S.Glas. in 1886; he then spent three years as a medical officer on board ship, visiting China, Japan, South Africa, and the West Indies. After this he practised at Spalding for seven years, and subsequently at Sunbury-on-Thames. In 1907 he was appointed medical officer of health to the Sunbury Council in succession to Dr. Palgrave, and he was also medical officer to the Staines Union, the Post Office, the Meropolitan Water Board, and the Sunbury Orphanage. During the war he was medical officer to the large depot of the R.A.S.C. at Kempton Park, and did much work for local members of the profession who were called up for duty with the Forces. He leaves a widow, a son, and a daughter. A colleague writes: Byham was a man of unusually good physique, and in his earlier life was known in Rugby circles as a stalwart forward; he was also a good cricketer, and an all-round sportsman. Although a very busy man during recent years, he was never too much occupied to listen to the story of the poorest patients, and his thoughtful cheery manner endeared him to all with whom he came in contact. The funeral service, on March 23rd, was largely attended by sorrowing friends of all ages, and was remarkable for the many beautiful wreaths.

The death of Alderman Dr. ARTHUR WILSON CHAPMAN, J.P., of Manchester, has removed one of the best-known figures in the public life, both medical and civic, of that city. Dr. Chapman was born in Birmingham in 1862, and went to Manchester as a boy. He was educated at St. Margaret's and the Grammar School, and graduated M.B., C.M. at Aberdeen University in 1886. Shortly afterwards he became immersed in general practice in Manchester, and rapidly built up a wide connexion, mainly in an industrial district. This, however, could not absorb all his energies, and in 1901 he was elected to the city council, becoming alderman in 1915. Here he interested himself in public health and infant welfare work, and more particularly in the tramway service, which he always spoke of as his chief hobby. In the medical world, among other offices, he held those of chairman of the Manchester Division of the British Medical Association for seven years; chairman of the Manchester Medical and Panel Committees for eleven years; and council representative on the Manchester Insurance Committee for fifteen years. In his student days he was well known as a Rugby football player, and a boxer above the average; in later years he was interested in lacrosse, becoming president of the North of England Lacrosse Association and other clubs. A journalist of no mean ability, a pronounced "family man," a lover of animals, his interests could scarcely have been wider, and in all his contacts with life Arthur Chapman earned and received not only the esteem but also the very real affection of all who knew him. To his intimates, and to them only, it was known that the latter years of his life were passed under the handicap of illness severe enough to have crippled any lesser man; but this was faced with courage and cheerfulness, and his zeal for work and service lasted to the end. The local profession has lost a great friend.

Medical News.

THE centenary of the Zoological Society of London will be celebrated on Monday, April 29th. A commemorative meeting will be held at 5 p.m. in the great hall of University College, followed by a dinner in the Gardens of the Society in Regent's Park.

THE annual luncheon of the Irish Medical Schools' and Graduates' Association will be held at the Queen's Hotel, Piccadilly, Manchester, on Wednesday, July 24th, at 1 o'clock sharp. Tickets, price 4s., may be obtained from the honorary secretary for the provinces, Dr. Falkland L. Cary, 67, King's Road, Harrogate. All Irish graduates, whether members of the association or not, are invited to attend the luncheon. The honorary secretary requests that applications for tickets may be sent to him as early as possible before the date of the meeting.

THE twelfth and last of the annual series of Sims Woodhead Lectures in connection with the People's League of Health Travelling Scholarship will be delivered to-day (Friday, April 19th) at 6 p.m., at 11, Chandos Street, Cavendish Square, W., by Dr. C. C. Worster-Drought, on the subject of decay and disease, natural and premature.

AT the next meeting of the Royal Sanitary Institute, to be held on Friday, April 26th, at 3 p.m., in the City Hall, Cardiff, discussions will take place on the new Local Government Act, on town planning, and on the proposed reconstruction, widening, and lowering of Cardiff Bridge.

THE annual meeting of the Medical Mission Auxiliary of the Church Missionary Society will be held in the Central Hall, Westminster, S.W., on Wednesday, May 1st, at 7.15 p.m. Tickets of admission may be obtained from the Superintendent, Loan Department, Church Missionary Society, Salisbury Court, E.C.4. A small number of reserved seats at 1s. each are available.

A DISCUSSION on the sterilization of the unfit will be opened by Lord Riddell at a meeting of the Medico-Legal Society, at 11, Chandos Street, W.1, on April 25th, at 8.30 p.m.

THE annual general meeting of the Tavistock Square Clinic for Functional Nervous Disorders will be held in the form of a luncheon party at the Hotel Russell, Russell Square, W.C.1, on Monday, May 6th, at 1.10 p.m.; Sir F. J. Willis will preside. The honorary director, Dr. H. Crichton-Miller, and the treasurer will present brief reports, and plans for the extension of the work of the clinic will be discussed.

THE Dr. Jessie Macgregor prize for medical science will be awarded next July to the applicant who presents the best record of original work in the science of medicine. This work may be unpublished or published, but in the latter contingency must not have been published earlier than three years before the month of July, 1929. The prize is of the value of £75, and is open to women who have graduated in medicine in the University of Edinburgh, or have taken the triple qualification, and who will have previously studied medicine for at least one year in Edinburgh. The successful applicant shall within three months of the award deliver a lecture to the medical profession in Edinburgh on the subject for which the prize has been awarded. Applications, marked "Dr. Jessie Macgregor prize in medical science," must reach the Convener of Trustees, Royal College of Physicians of Edinburgh, not later than May 31st.

LORD DAWSON OF PENN will distribute the prizes and certificates to students of the London Hospital Medical College (University of London) on Friday, June 28th.

THE first course for the M.R.C.P. diploma organized by the Fellowship of Medicine will extend from May 7th to June 28th, and consists of sixteen lectures by well-known authorities on Tuesdays and Fridays, at 8.30 p.m., in the lecture hall of the Medical Society of London, 11, Chandos Street, Cavendish Square. Two courses are now in progress: one in medicine, surgery, and gynaecology, at the Royal Waterloo Hospital, will conclude on May 4th, and the other in neurology, at the West End Hospital for Nervous Diseases, and consisting of lecture-demonstrations at 5 p.m. each day, will finish on May 10th. A comprehensive course begins on April 29th in diseases of the throat, nose, and ear at the Central London Throat, Nose, and Ear Hospital, and continues for three weeks. Starting also on April 29th is a month's course in psychological medicine at the Maudsley Hospital. From May 6th to June 1st a course in venereal diseases will be conducted at the London Lock Hospital. From May 2nd to June 1st the London School of Dermatology will hold a special course consisting of clinical instruction and formal lectures. Practical pathological demonstrations can be arranged if desired. From May 27th to June 8th an afternoon course, under the direction of Dr. Eric Pritchard, will be held at the Infants Hospital. Detailed syllabuses of the foregoing courses, information relating to the general course of work at the various London general and special hospitals, and copies of the *Post-Graduate Medical Journal* may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE Central Midwives Board for England and Wales met on April 4th, with Sir Francis Champneys in the chair. The standing committee reported that it had appointed the following to be members of the Approvals Subcommittee: Miss A. Davies, Miss E. M. Doubleday, Dr. J. S. Fairbairn, Miss E. E. Greaves, Dr. R. A. Lyster, Miss A. A. I. Pollard, and Mrs. E. Richmond. Approval for the year ending March 31st, 1930, was given to the list of examiners, the list of lecturers and institutions where lectures may be delivered, and the list of institutions, homes, and midwives at which, or under whom, midwives may be trained.

As announced in our advertisement columns, applications are invited for the Dickinson Pathology Scholarship and for the Dickinson Travelling Fellowship in Medicine. Candidates for the former, value £75, must have received their full course of instruction in pathology, medicine, and surgery at the University of Manchester and the Manchester Royal Infirmary. The Travelling Fellowship is of the value of £300, and candidates must have taken out the full course of clinical instruction required by their examining bodies in the Manchester Royal Infirmary and the University of Manchester. The scholarships are both tenable for one year. Full particulars and a copy of the regulations may be obtained from Mr. F. G. Hazell, secretary to the trustees, Manchester Royal Infirmary, to whom applications must be sent by May 2nd.

THE issue of *Medizinische Klinik* for March 28th is dedicated to the memory of the distinguished Viennese surgeon, Theodor Billroth, on the occasion of the celebration of the centenary of his birth on April 26th, 1829, and contains articles on him by Professor G. Lotheissen, and also Drs. I. Fischer and K. Feri of Vienna and Professor W. Körte of Berlin.

THE March issue of *The Mission Hospital*, published by the Church Missionary Society, London, is devoted to maternity and child welfare, and contains accounts of the progress being made in this respect under the auspices of the society in different parts of the world, including China and Southern and Central Africa.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the *British Medical Journal, Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

LORD LISTER.

"J. S. R." asks if any reader can tell him where he could obtain a small bust of the late Lord Lister.

INCOME TAX.

Succession followed by Introduction.

"H. D. O." sold his practice as from December 31st, 1928, but remained acting, according to the agreement for sale, as assistant to the purchaser during the following three months. What adjustment can he claim, and what is his liability—if any—for the year 1929–30?

*** We assume that the practice was a "sole" practice. Our correspondent can have his liability for the year ended

April 5th, 1929, reduced to the amount of his earnings for that year—for example, three-fourths of the 1928 profits *plus* the "assistant" earnings for the last three months—but is liable, on the other hand, to have the assessment for the year to April 5th, 1928, adjusted, if the Revenue desire it, to the amount of the earnings for that year. As regards 1929-30, he will apparently have ceased his connexion with the practice, and will not be liable to an assessment for proceeds thereof—cash receipts coming to hand after December 31st, 1928, represent the harvesting of income the liability for which has been accounted for as it was being earned.

Expenses of Research incurred by Lecturer.

"CH.M." holds a University appointment; the regulations provide that he "shall be expected to engage in higher study and research." The research programme was apparently discussed with the Dean of the Faculty, and definite instructions were given by him as to the work to be done and places to be visited for that purpose. "Ch.M." incurred expenses amounting to £54 in carrying out those instructions, and has had the deduction of that amount from his assessable emoluments refused after a personal appeal to the General Commissioners.

*** *In our opinion this is a borderline case, and we are not* clear that "Ch.M.'s" claim is well founded in law, especially as it is not shown that the Dean has the legal right of prescribing precisely what work is to be done without the volition of the lecturer. Expenses wholly, exclusively, and necessarily incurred in fulfilling the condition attached to the appointment would be allowable, but other purposes are also served—which makes the "exclusively" an awkward stipulation—and it is possible that "Ch.M." might have adopted some less expensive means of research. The technical points mentioned by "Ch.M." we do not regard as of much moment; an appeal cannot be made to the Special Commissioners, as that body is alternative to the General Commissioners, and not a superior tribunal, and the only steps "Ch.M." can take now for the year in question is by way of appeal to the High Court on the point of law. He might be well advised to protect his right to do so by paying one guinea to the Clerk to the Commissioners with a request for a statement of the case. When he receives the case he can better decide whether it will be worth his while to incur further expense in the matter.

Motor Expenses Exceed Allowance.

"H. A. C." has to have a car for use in connexion with his work as district tuberculosis officer. He receives an allowance at the rate of 5d. per mile but, owing in the main to rather frequent renewals of his car, his actual expenses, including depreciation, loss on exchange, etc., have been in excess of the amount so calculated. Can he claim to deduct that excess for income tax purposes?

*** *He will* have to prove that the excess was expended out of his salary wholly, exclusively, and necessarily in the performance of his duties. In effect this implies that the 5d. per mile allowance is inadequate; the special and apparently rather unfortunate circumstances of his case are difficult to introduce in view of the word "necessarily," and we cannot but consider his chance of success in proving that inadequacy to be somewhat *slight*.

LETTERS, NOTES, ETC.

PUBLIC HEALTH CONGRESS IN ZÜRICH.

DR. E. W. HOPE and DR. T. N. KELYNACK (honorary secretaries, Royal Institute of Public Health, 37, Russell Square, W.C.1) write: The preliminary programme for the 1929 Zürich Conference of the Royal Institute of Public Health, May 15th to 20th, has now been issued and a copy can be forwarded on request. We are assured of the most cordial welcome by the Swiss National Government, the authorities of the canton, city, and the University of Zürich, and by the leaders of the medical school of Zürich. Invitations have also been received to visit various health stations in Switzerland. The Government gives a concession of 50 per cent. on the State railway; free transportation will be provided on the Rhaetian Railway (Chur to Davos and on the railways Chur to Arosa, Sierre to Montana, and Aigle to Leysin. The local authorities at each of these well-known centres are most anxious to welcome as many members of the congress as possible. We are further assured by the Czechoslovak Minister, Mr. Jan Masaryk, of a hospitable reception for those who may find time after the congress to extend their journey to the two great Czechoslovak spas of Carlsbad and Marienbad. In order to complete arrangements for the comfort of members of the congress desiring to participate in the extensions, it is essential that we should know immediately which of the visits members will desire to take. Particulars regarding the extensions and the routes to be traversed, together with information as to the expenses to members of the congress, will be forwarded on application; non-members may accompany members, but will not be able to enjoy all the special privileges. The inclusive cost of the visit to the congress at Zürich will range from £10 4s. 6d. for the short sea route, second-class travel on the Continent and hotel accommodation, to £12 12s. 6d. for first-class travel throughout and hotel accommodation. Full particulars regarding the different extended journeys available after the conference, together with a list of the various hotels in Zürich, are available on demand, and it is earnestly requested that all who propose to attend the conference will communicate with us as soon as possible.

POISONING FROM EXHAUST FUMES.

"M.D., B.S." (London, W.1) writes: The recent fatal accident that arose from the driver of a public motor vehicle being momentarily overcome by drowsiness makes one wonder what precautions are taken, and what authority, if any, is responsible for their enforcement, to protect drivers, and through them, their passengers and other road users, from conditions leading to such accidents. The average *doctor* is a motorist of necessity, and many of us know only too well how almost hypnotic may be the effect of long driving on a tired brain and how easy it is to be overcome by momentary sleep, even in an open car with the wind blowing freely round the screen. If engine fumes are added, how intensely might this drowsiness be increased! In some motor buses, as I can personally testify, engine fumes may be markedly noticeable even to a passenger seated by an open window. How much more potent must they be in an ill-ventilated cabin, where the engine "breather" may be situated immediately below the driver's feet! Our factories and workshops are subject to strict inspection for the sake of the health of the employees. Is there any inspection of the conditions under which a bus driver works—conditions which may concern not only his own health, but also the safety of his passengers and other road users? If so, why does one hear, at least in some provincial districts, of men driving for three and four consecutive "long days," with only four hours' sleep between? Why does one hear of these men staggering from their driving cabins and clinging to some support at the roadside while they breathe in fresh air to relieve the uncontrollable drowsiness and giddiness which attacks them, and of others who have to "go sick" with gastro-intestinal attacks and other symptoms referable to exhaust gas poisoning? Perhaps some readers of the *Journal* may be able to mention cases they have treated of exhaust gas poisoning in public vehicle drivers.

PAINFUL SHOULDER.

"PODAGRA," continuing this discussion, which began with Mr. P. B. Roth's letter on December 22nd, 1928 (p. 1156), writes: Being one of the many elderly fellow-sufferers, I quite agree with "T. F." (March 16th, p. 534) as to the improbability of it being due to synovitis, there being no obvious signs of inflammation in the shoulder-joint. I could not raise my elbow, which was trying this side of the Atlantic; as to getting my hand into my trousers pocket, that I must admit has always been an inherent difficulty, for I keep my small change there. I also have the pain and occasional tenderness over the insertion of the deltoid, but it should be remembered that the insertions of the teres major, latissimus dorsi, and pectoralis major are in the bicipital groove, which is immediately above and beneath the deltoid. The action of this group of muscles is to rotate the humerus inwards and bring it to the side; now if, owing to the sudden contraction of this group of muscles, any of the fibres are torn, together with their sensory nerve endings (muscle spindles), a traumatic fibrositis is set up, similar to lumbago. The treatment I am undergoing, after subjecting the painful area to radiant heat, is forcible extension, advocated by Romer years ago. After half a dozen sittings my movement has been considerably increased and the pain lessened.

ANAESTHESIA FOR COLLES'S FRACTURE.

DR. WILLIAM HAIG (Crieff, Perthshire) writes: In his letter in the *Journal* of April 13th (p. 705) Mr. G. H. Fagge says "it must, however, be admitted that in some cases of Colles's fracture in elderly and infirm women a bad result is preferable to the risk which a general anaesthetic would entail." I wonder if he has considered the use of "twilight sleep" as a substitute for the general anaesthetic. In two such cases recently—both women over 70—I injected a sterile solution of tabloid hyoscine compound B and left to continue my visits elsewhere; when I returned, on each occasion within a couple of hours, I found the patient sufficiently anaesthetized and relaxed to enable me to set the fracture satisfactorily.

CAUTION.

ON April 3rd, 1926 (p. 640), and again on August 27th, 1927 (p. 372), the *British Medical Journal* cautioned readers against begging letters from a Mrs. [illegible] rom recent information received it appears [illegible] is continuing to write to members of the [illegible] and they are strongly advised to forward such begging letters to the secretary of the Charity Organization Society, Denison House, Vauxhall Bridge Road, London, S.W.1.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 45, 47, 48, 49, 52, 53, and 54 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 50 and 51.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *151*.

THE HOLBORN SURGICAL INSTRUMENT CO., LTD., 26, THAVIES INN, HOLBORN CIRCUS, E.C.1

FOR DEAFNESS

Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports.

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, which delighted Medical Men at the recent B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

HOME TESTS ARRANGED FOR DOCTORS AND PATIENTS.

Prescribed in numerous cases *of nervous and heart disorders, also rheumatic conditions, etc.*

The active substances of the extracts from cone bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

The Chair will be taken by TOM JAYS, Esq., M.R.C.S., L.R.C.P. (Principal of Livingstone College), and the Speakers will be:

H. T. HOLLAND, Esq., C.I.E., M.B., F.R.C.S.Edin. (Baluchistan).

Rev. W. WILSON CASH, D.S.O. (Gen. Secretary, C.M.S.).

NORMAN E. COOK, M.B., B.S.Lond., D.T.M. & H. (Recruit).

Tickets of admission may be obtained from the Superintendent, Loan Department, Church Missionary Society, Salisbury Square, E.C.4. There will be a small number of reserved seats at 1/- each.

St. Mary's Hospital, Institute OF PATHOLOGY AND RESEARCH.

Principal: Sir ALMROTH E. WRIGHT.

Applications are invited from qualified medical practitioners for a RESEARCH STUDENTSHIP. This will be tenable for six months, and may be renewed for second period of six months.

The Institute comprises the following departments: Anatomy and Embryology, Physiology, Pathology, Chemical Pathology, Clinical Bacteriology, Systematic Bacteriology, and Immunology.

The student, who will receive an honorarium at the rate of £200 per annum, may elect to carry out his researches in any one of these departments, and would be required to work under the direction of the head of the department concerned.

Preference will be given to old St. Mary's Students.

For further particulars apply to the Secretary, Institute of Pathology and Research, St. Mary's Hospital, Paddington, W.2, to whom applications must be sent not later than April 30th.

The Royal Infirmary of EDINBURGH.

SECRETARY AND TREASURER.

The Managers invite applications for this post which will be vacant at the close of the current year. Priority of consideration will be given to candidates having some knowledge of law and also of accounting.

The commencing salary will not be less than £900 per annum, and the successful candidate will be required to attend daily from September 2nd next, and to take over full responsibility on January 1st, 1930. A note of the principal duties of the joint offices can be obtained on application to the Superintendent. Candidates, who must state their age and give full particulars of their business training and experience, are requested to forward, by May 15th, twenty eight copies of their letter of application, together with recent testimonials (not exceeding four in number) to the Superintendent, Royal Infirmary, Edinburgh.

April 10th, 1929

THIRD ASSISTANT MEDICAL OFFICER.

A Third Assistant Medical Officer (male) is required at the PLUMSTEAD AND DISTRICT HOSPITAL, Plumstead High Street, S.E.18.

Candidates must be doubly qualified and registered.

The gentleman appointed must have held resident Hospital appointments and have experience in the administration of anæsthetics. He will be required to carry out *such duties* as may be assigned to him by the Medical Superintendent, and, should occasion arise, to assist at any of the other establishments under the control of the Guardians.

Salary £300 per annum, rising £25 annually to £350 per annum, with residence and rations, subject to deductions under the Poor Law Officers Superannuation Act.

Further particulars of the appointment may be obtained by *personal application* to the Medical Superintendent between the hours of 10 a.m. and 1 p.m., *or by letter.*

Applications, upon forms to be obtained from my office, as under, upon receipt of a stamped, addressed, foolscap envelope, or by personal application, must be returned to me not later than April 29th.

The appointment will be made by the Guardians at their meeting on May 16th. The gentlemen selected to *appear before the* Guardians will be notified, and if they have not had an interview with the Medical Superintendent they will be expected to call on him before that date.

By Order,
Union Offices, Plumstead High St., S.E.18.
ARTHUR HOLDER,
Clerk to the Guardians.
April 15th, 1929.

Liverpool Port Sanitary AUTHORITY.

ASSISTANT PORT MEDICAL OFFICER.

The Corporation of the City of Liverpool, as Port Sanitary Authority, require the services of an Assistant to the Medical Officer of Health, whose duties will be in connection with the Tidal Inspection of Vessels, the Medical Inspection of Aliens, and such other duties as may from time to time be assigned to him.

The salary will commence at £700 per annum, increasing to £800 per annum by annual increments of £50.

Candidates must possess a registrable Medical and Surgical qualification, and should hold a Diploma in Public Health, and their age must not exceed 35 years.

The person appointed will require to devote whole-time service to the duties specified, and will be subject to the Superannuation provisions of the Liverpool Corporation Act, 1921.

Canvassing of members of the Council is strictly prohibited.

Applications, stating age, qualifications, and past experience, accompanied by copies of recent testimonials, should be addressed to the Chairman of the Port Sanitary and Hospitals Committee, under cover to the undersigned, and delivered not later than May 6th.

Envelopes to be endorsed "Assistant Port *Medical Officer.*"

Municipal Buildings, Liverpool, W.
WALTER MOON,
Town Clerk.
April 10th, 1929.

Nottinghamshire County Council

APPOINTMENT OF ASSISTANT SCHOOL MEDICAL OFFICER (male).

Applications are invited for the appointment of a whole-time Assistant School Medical Officer at a salary of £600 per annum, with travel*ling expenses in addition according to the scale* approved by the County Council.

Candidates must be fully qualified and registered medical practitioners of at least three years' standing, with a Diploma of Public Health, and in addition must have recent experience in the administration of anæsthetics for dental operations (chiefly Nitrous Oxide), practical knowledge of carrying out refractions and of the special examination of children for Mental Deficiency.

The person appointed will be a Member of the Staff and act under the control and direction of the County Medical Officer of Health, and will be required to reside in a part of the County to be approved by the Education Committee

The appointment will be terminable by three months' notice on either side.

Applications on the prescribed form (which may be obtained on application to me), accompanied by copies of not more than three recent testimonials, should be forwarded to County Medical Officer, Shire Hall, Nottingham, not *later than April 27th.*

Shire Hall, Nottingham.
K. TWEEDALE MEABY,

April 15th, 1929.

Parish of St. John, Hampstead.

The Guardians of the above Parish require a JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER at their NEW END HOSPITAL, to start duties on June 1st. Appointment six months, renewable at option of the Guardians. Salary £200 per annum, with board, lodging, and washing. Further *particulars* can be obtained from the Medical Superintendent. Applications to be sent to my office on or before 10 a.m., Thursday, May 2nd.

Guardians' Offices, New End, Hampstead.
H. WESTBURY PRESTON,
Clerk to the Guardians.

County Council of Middlesex.

THE COUNTY (TUBERCULOSIS) SANATORIUM, HARLEFIELD, MIDDLESEX.

THIRD ASSISTANT RESIDENT MEDICAL OFFICER.

The County Council invite applications for the post of Third Assistant Resident Medical Officer (male) at the above Institution at a salary of £400 per annum (no bonus), with *board, lodging,* and laundry.

Candidates must be registered medical practitioners, not over 35 years of age, unmarried, and of British nationality. They must have held resident hospital appointments. Practical experience in the diagnosis and treatment of tuberculosis (including the induction of artificial pneumothorax) will be an additional qualification.

The officer appointed will be required to devote his whole time to the duties of the post, and to contribute to the County Council's Superannuation Fund. For the latter purpose he will be required to pass such medical examination as the County Council may direct.

The appointment is terminable by one month's notice on either side.

Applications, stating (1) name, (2) age, (3) experience, accompanied by copies of not more than three recent testimonials, must be received by the undersigned not later than Saturday, April 27th.

Canvassing is prohibited.

Guildhall, Westminster, S.W.1. April 5th, 1929. ERNEST S. W. HART, Clerk of the County Council.

City and County of Kingston-upon-Hull.

ASSISTANT MEDICAL OFFICER OF HEALTH.

The Corporation of Hull invite applications from medical men and unmarried or widowed medical women, under the age of 40 years and of not less than three years' standing in their profession, for the post of Assistant Medical Officer of Health.

Salary £600 per annum, rising by annual increments of £25 to £700.

The appointment is subject to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The successful candidate will be required to devote the whole of his or her time to the duties of the office, which consists mainly of work in the Maternity and Child Welfare Department, the School Medical Service and the Tuberculosis Department but may also include duty in connection with other of the Health Services of the City of Hull.

Candidates should have had special experience in Maternity and Tuberculosis work.

A [illegible] application may be obtained from the undersigned and must be returned to him, duly completed on an envelope endorsed "Medical Officer of Health"), together with [illegible] recent testimonials, not later than [illegible] must post on Monday, May 6th to the Department.

W. ALLEN DALEY, Medical Officer of Health.

Guildhall, Hull.

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. PARTNERSHIP.—LONDON.—In a populous district, the half share of an old-established middle and working-class Practice, worth over £2,000 p.a., including panel of 1,300. Visits 3/6 to 10/6. Expenses light, car not necessary. House contains professional accommodation, 2 reception, 2 bedrooms, bathroom, etc. Held on lease at rental of about £60 p.a. Premium 2 years' purchase.
2. SOUTH COAST.—Popular and favourite Watering-place.—Old-established increasing mixed-class PRACTICE, worth last year nearly £1,600, including panel of over 1,150, and offering further scope. Visits 3/6 upwards. Mids. from 4 gns.. About 30 cases yearly. House contains eight rooms, with usual offices, and garden. Price £1,450 (at least £1,000 can be obtained on mortgage). Held by Vendor, who will give efficient introduction, over 9 years.
3. SHEFFIELD.—Better-class non-panel and non-dispensing PRACTICE, averaging approximately £3,000 p.a., and offering good scope. Suitable house can be obtained in developing district. Premium 1½ years' purchase, with 12 months' introduction.
4. PARTNERSHIP.—OUTLYING WESTERN SUBURB.—A one-third or one-half share is for disposal in a well-established mainly better working-class Practice, producing over £2,300 p.a. Appointments worth about £100 p.a., and panel of 1,400. Fees from 2/6 to 21/-. Lowest midwifery 3 gns. Purchaser (if single) could reside in rooms, or suitable house obtainable. Premium 2 years' purchase.
5. SOUTH-WEST OF ENGLAND.—Large Thriving Hospital Town.—PARTNERSHIP.—The half or five-ninths share in an old-established better and middle-class non-panel general and surgical Practice can be acquired by a suitable gentleman possessing the F.R.C.S. degree. Receipts for the past three years average over £5,000 p.a. Good house, with ample accommodation, at present held on lease with option to purchase. Premium 2 years' purchase.
6. SOUTH-WESTERN COUNTY.—LARGE SEAPORT TOWN.—Old-established mixed-class PRACTICE averaging over £3,000 p.a., including panel of 2,100. Visits 3/6 to 10/6; midwifery [illegible] of late) 3 gns. upwards, about 30 cases yearly. Ex[illegible] necessary). House contains professional [illegible] 6 bedrooms, bathroom, etc. Large garden, garage. Vendor's freehold price £2,800, of which £1,200 can remain on mortgage, or might be rented at £96 p.a. Premium 1½ years' purchase, £3,000 down and balance by arrangement.
7. BUCKINGHAMSHIRE.—Country PRACTICE, situated in delightful district within 50 miles of London.—Old-established mixed general Practice, producing a steady average income of £2,000 p.a. Panel brings in about £700 p.a. Moderate expenses. Fees from 2/6 to 21/-. Under 30 midwifery cases yearly. Exceptionally nice and well-situated house, with 2 reception, 6 bedrooms, etc.; separate entrance to professional rooms. Large garden, with tennis court. Price for freehold £1,500. Excellent sport. Premium £3,000.
8. HOME COUNTY.—Within 40 miles of London.—In small Village (with large surrounding population) in pleasant district, old-established mixed and increasing PRACTICE, worth last year nearly £3,600, including Union and Vaccination over £100, and panel producing over £1,150 Railway station in place. House contains surgery and waiting rooms (separate entrance), 2 reception, 4 bedrooms, bathroom, etc., large garden. Gas, electric light available. Price for freehold £2,500, part mortgage. Premium 1½ years' purchase. Good society, sport, etc. Vendor keeps an Assistant, but investment would admirably admit of taking a partner later on, as houses available.
9. HERTS.—PARTNERSHIP.—A one-third share, and up to one-half later, is for disposal in an old-established Practice, averaging about £2,000 p.a., and offering good scope for increase. Fees 3/6 to 15/-. Not much midwifery. Ingoing partner should be experienced and between 30 and 40 years of age. Sport of all kinds. Premium 2 years' purchase.
10. ESSEX — Small Country Town — Well-established and increasing Practice, producing about £800 for last 12 months, including panel of 525 and appointments worth about £60. Advice and medicine chiefly 3/6 to 7/6, visits 3/6 to 21/-, medicine extra. Mids. (discouraged) 2 to 5 gns. Exceptionally nice house, with lounge hall, 3 reception, 5 bedrooms, good professional rooms, and usual offices. Hot water supply. Electric light. Large garden, with tennis court. Garage for 2 cars. All in perfect order. Price for freehold £3,100. Premium 1½ years' purchase.
11. WITHIN ONE HOUR OF LONDON (good train service).—Old-established mixed-class PRACTICE, offering good scope. Average income about £600. Fees 2/6 to 7/6. Not much midwifery. Easily worked. Semi-detached house in good condition, with 2 reception, 6 bedrooms, etc. Surgery and waiting room. Garden. Rent on lease £65 p.a. Premium 1½ years' purchase, or near offer.
12. LONDON, NORTH.—Old-established non-panel PRACTICE, offering good scope, as Vendor has refused work owing to ill health. Average income for past 3 years £670. Fees 2/6 to 7/6. Not much midwifery from 3 gns. Ten-roomed house, with bathroom. Can be bought or rented on lease. Premium £1,000.
13. SOUTH-WEST OF ENGLAND.—PARTNERSHIP.—A one-half share in a very old-established Practice situated in an attractive small town, amidst [illegible] and within easy reach of the Coast. Gross c[illegible] st year over £2,900. Panel of 1,218, which, together with appts., brings in about £900 p.a. Moderate expenses. Visits 2/6, plus mileage and medicine 2/6 and 3/6 extra. Very suitable house, with 3 reception, 4 bedrooms, and usual offices. Garden. Price for freehold £750, of which £350 on mortgage. Premium 2 years' purchase.
14. NORTH DEVON.—COUNTRY TOWN.—A one-third share (with increase up to one-half later) in a very old-established and increasing mixed-class PRACTICE, averaging about £3,000 p.a., including panel of over 2,100, and appts. worth nearly £150. Fees 3/6 to 10/6. Midwifery 2 to 7 gns. Choice of houses. Sport of all kinds and schools. Premium 2 years' purchase, part by arrangement necessary. Preliminary outdoor assistantship offered at a salary of £450 p.a. Scotch Graduate preferred, about 30 years of age.
15. CORNISH RIVIERA.—In a small but rapidly growing town (pop. 5,000—6,000) on the Coast, an old-estab. PRACTICE producing last year over £1,000, including appts. and panel of 550 to 600. Opposition weak. Delightful residence, standing in own grounds of 1½ acres (croquet and tennis lawns, etc.) and eminently suitable for Resident Patients, which Vendor has been in the habit of taking. Contains professional rooms, 4 reception, 9 bedrooms, 2 bathrooms, etc. Water and electric light. Garage. Price for freehold £4,000. Prem. £1,500.
16. LONDON, SOUTH-WEST.—Within three miles of Charing Cross.—PARTNERSHIP.—A half share, with succession to the whole in about two years, in a very old-established non-panel Practice, held by Vendor 26 years. Steady average income of £2,300. Surgery fee 2/6 and 3/6, visits mainly 5/- and 7/6. Very little midwifery. Good house, in main road, with garden. Held on lease, with nearly 15 years to run, at a rental of only £55 p.a. Premium 2 years' purchase. Very good scope for increase.
17. LANCS. — LARGE TOWN, within easy reach of Manchester and Liverpool.—Old-established PRACTICE. Average income for past 12 months £1,500, including panel of nearly 1,500. Fees 2/6 to 10/6. Good house, with nice garden. Can be rented on lease at £65 p.a. Premium only 1½ years' purchase for prompt sale.
18. NEAR SOUTH COAST.—Old-established mixed-class PRACTICE, situated in delightful country district within easy reach of two favourite towns. Income last year over £1,600. Panel of about 700. Fees 3/6 to 21/-. Midwifery 2 to 7 gns; very few cases. Good house, standing in its own grounds, with 2 reception, 5 bedrooms, etc. Garage for two cars. Sport of all kinds, and good schools within reach. Premium £2,250.
19. LONDON, NORTH.—Old-established centrally situated mixed general PRACTICE. Income for the immediate past year £3,500, including panel list of 2,200 and appointments about £125. Fees, advice, and medicine 2/6 to 5/-. Visits 5/- to 7/6. Under 50 midwifery cases yearly from 4 to 8 guineas. Assistant and motor are required. Good house can be rented on lease, or freehold would be sold. Premium £6,000, part by arrangement. Long introduction.
20. CHANNEL ISLANDS.—Old-established general PRACTICE Present income approximately £700, but large scope. Advice and medicine 3/6 to 10/6, visits and medicine 5/- to 15/-. Midwifery refused. Commodious house, with 2 reception, 6 bedrooms, etc. Vendor's freehold. Good schools. Price for practice and house £3,000.
21. KENT.—COAST TOWN.—Small but increasing middle and working class PRACTICE, producing for last 12 months nearly £600. Panel of 560. Visits 3/6 upwards. Not much midwifery at from £3 3. Double-fronted eight-roomed house, with three-quarters of an acre of garden. Premium £900.
22. X-RAY AND ELECTRO-THERAPEUTIC PRACTICE. — In a large Hospital Town, within 80 miles of London, a well-established connection averaging nearly £1,000 p.a. (last year £1,059) is for disposal for reasons which can be satisfactorily explained. Patients upper and middle-class. Fees 1½ to 15 gns. House situated in pleasant position, with ample professional accommodation, and 4 rooms, dressing room, bathroom, etc. Premium £1,500. Electric plant (which has been valued) £670 extra. Vendor is on staff of Hospital (nearly 300 beds) and successor will be appointed.

Full Schedule of Terms and Conditions will be forwarded on application.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

$C_8 H_{10} N_4 O_2 + H_2 O$

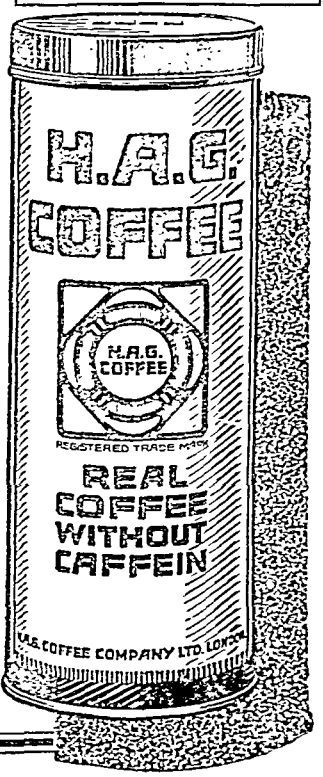
THE injurious action of caffein, to which the ailing, reconvalescents and those in good health become liable by the habitual or excessive consumption of coffee and tea, is causing an increased interest in the medical world. There is already a comprehensive literature dealing with this subject; in many cases it absolutely bans the consumption of beverages containing caffein.

THE physician who is solicitous with regard to the welfare and ailments of his patients will specially value the knowledge that **H.A.G. COFFEE**—a caffein-free berry coffee—is obtainable, which in respect to aroma and palatableness, affords the same sense of enjoyment as ordinary coffee containing caffein, but without its harmful action on the cardiac, the nervous, and the vascular system.

WITH **H.A.G. COFFEE** the caffein is extracted from the unroasted coffee bean by a patented process, until only a slight, non-effective trace remains. Previous to this treatment, the coffee beans undergo a most thorough cleansing.

CAFFEIN-free **H. A. G. COFFEE** can confidently be recommended as the best and most valuable health coffee, and, in order to give members of the Medical Profession an opportunity of personally appreciating the hygienic characteristics of **H.A.G. COFFEE**, we shall be pleased to send a sample and literature free on request.

H.A.G. Coffee can be obtained in 2 sizes, price 3/2 and 1/8, either ground or in the bean. If your grocer has no stock we will supply post free upon receipt of your remittance



H.A.G. COFFEE CO. LTD.

COAGULEN-CIBA IN HÆMORRHAGE

Five correspondents in *The British Medical Journal*, July 28th, 1928, p. 182, testify to the value of Coagulen-Ciba in Hæmophilia.

Reports on the successful administration of Coagulen-Ciba were published in *The Lancet*, October 31st. 1925, p. 918, Intestinal Hæmorrhage; *The Lancet*, June 13th, 1925, p. 1238, Hæmoptysis treated by Intrapulmonary Injections; *The Lancet*, January 24th, 1925, p. 176, Hæmorrhage following Tonsillectomy.

Three cases (two Hæmoptysis, one Bowel Hæmorrhage) successfully treated with Coagulen-Ciba by the mouth are reported in the *Journal of the Royal Naval Medical Service*, No. 1, Vol. XII, pp. 64-65.

Full particulars and reports to Physicians on request.

IMPORTANT ANNOUNCEMENTS

JUST PUBLISHED. IN THREE VOLUMES. Medium 8vo. With 1,072 Illus. £6 6s. net.

KAUFMANN'S PATHOLOGY

Authorized Translation of the "Lehrbuch der Pathologischen Anatomie."

By **Dr. EDUARD KAUFMANN,** Professor of General Pathology and Pathological Anatomy and Director of the Pathological Department, University of Göttingen, etc. Translated by **STANLEY P. REIMANN,** M.D., Pathologist and Director of the Research Institute of the Lankenau Hospital, Philadelphia, etc.

EXTRACT FROM PUBLISHERS' NOTE:—Kaufmann's Pathology is a work of international repute. The German editions are widely consulted by those who read the language, and there has also been published an Italian edition . . . . The work is a most complete pathology, general and special. The length and scope of each chapter have been increased to present a complete picture of our present objective knowledge, and the subjects considered of most importance to practising physicians have been emphasized and given in greater detail.

JUST PUBLISHED. FIFTH EDITION. Revised and Greatly Enlarged. Medium 8vo. With 249 Illus.

AN INDEX OF SYMPTOMATOLOGY

By Twenty-six Distinguished Contributors.

Edited by

H. LETHEBY TIDY, M.A., M.D.Oxon., F.R.C.P.Lond.,
Asst. Phys., St. Thomas's Hospital; Con. Phys., Royal Northern Hosp.

This book is intended to provide an account of the symptomatology of diseases. The general object has been to give a clear and reasonably full description of the clinical manifestations of each disease, without dwelling unduly on minor complications and variations.

"Should help considerably in the solution of difficult diagnostic problems. The articles, which cover all branches of medicine, surgery, gynæcology, and the specialties, are tersely written and well up to date . . . a volume worthy of the series to which it belongs."—B.M.J.

Health, Disease, and Integration

By

H. P. NEWSHOLME,
M.A., M.D., F.R.C.P., B.Sc., D.P.H.

This study of the basic factors underlying the maintenance of health is based on an intimate analysis of a series of cases of encephalitis lethargica. The principles of integration which the author outlines are applied to certain social and spiritual problems.

RADIUM

For Therapeutic & Physical Purposes

We are the sole agents for the British Empire (excluding Canada) of the Anglo-Belgian Mining Corporation, The Union Miniere du Haut Katanga (Radium Section), the producers of practically the whole of the world's output of radium. We are prepared to give information and advice regarding the use of radium, and to supply radium in any form, accompanied by an official signed guarantee of measurement and purity. We have during the past few years supplied practically all the large hospitals using radium and also the leading radium therapists and physicists.

British Medical Association

MANCHESTER

JULY 22nd to JULY 26th, 1929, inclusive.

THE

ANNUAL EXHIBITION

OF

SURGICAL INSTRUMENTS and APPLIANCES,
DRUGS, FOODS, BOOKS, Etc.,

will be held in the

City Exhibition Hall, Deansgate, Manchester

EXHIBITION HOURS

Mon., July	22nd.	2 p.m. to 6 p.m.
Tues., „	23rd.	9 a.m. to 6 p.m.
Wed., „	24th.	9 a.m. to 6 p.m.
Thurs., „	25th.	9 a.m. to 6 p.m.
Fri., „	26th.	9 a.m. to 6 p.m.

FORMAL OPENING BY PRESIDENT-ELECT

The Exhibition will be formally opened by the President-Elect, accompanied by other Officers of the Association and the Members of the Representative Body, on Tuesday, July 23rd, at 9 a.m.

Reception Room and Information Bureau.

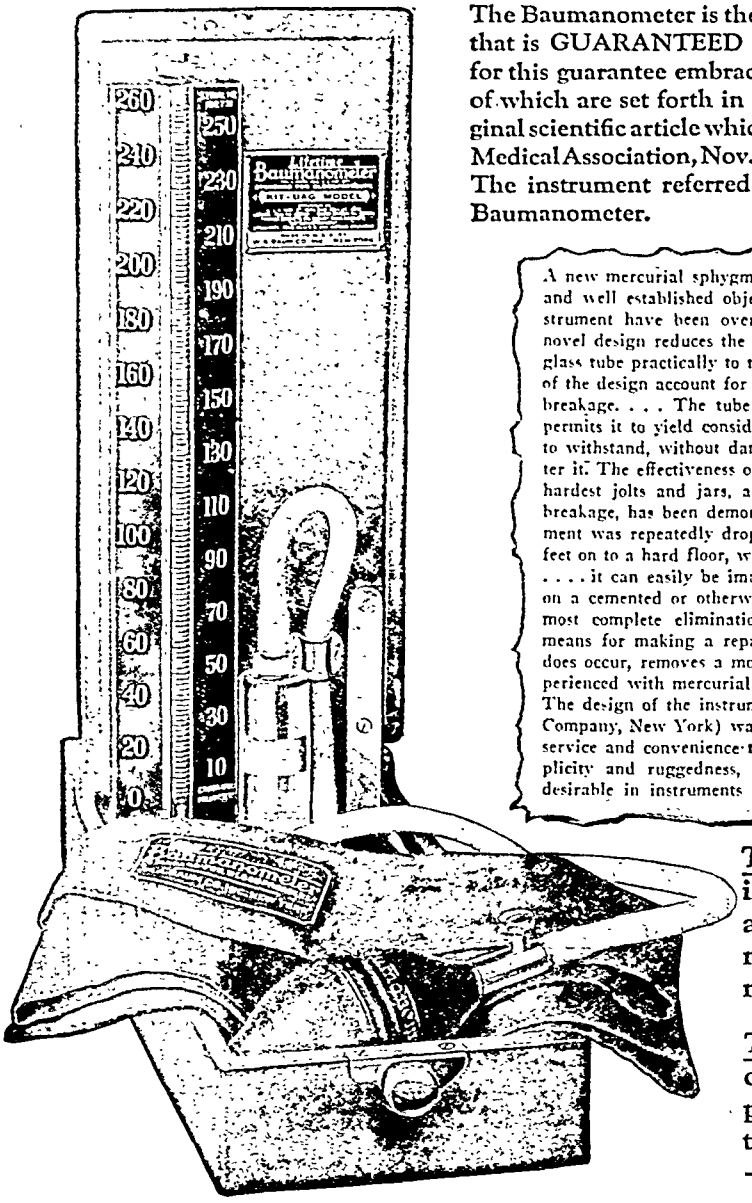
The Reception Room and Information Bureau will also be situated in the CITY EXHIBITION HALL, where all Members will register their attendance at the Meeting, obtain all tickets for functions, and receive information in connection with the Meeting.

Plan of Exhibition, with full particulars, now available.

Apply, L. FERRIS-SCOTT, F.C.A., Financial Secretary and Business Manager, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

The *Lifetime* GUARANTEE

—*its TRUE significance*



The Baumanometer is the only instrument in all of the world that is GUARANTEED against glass breakage. The *reason* for this guarantee embraces certain facts, the more important of which are set forth in the following excerpts from an original scientific article which appeared in the Journal American Medical Association, Nov. 20, 1926, Vol. 87, pp. 1742 and 1743. The instrument referred to, of course, is the new Lifetime Baumanometer.

> A new mercurial sphygmomanometer in which several important and well established objections to this type of bloodpressure instrument have been overcome has been developed recently. Its novel design reduces the possibility of accidental breakage of the glass tube practically to the vanishing point . . . Several features of the design account for the almost complete elimination of glass breakage. . . . The tube is held in a resilient mounting which permits it to yield considerably to side and end thrusts and thus to withstand, without damage, shocks that would otherwise shatter it. The effectiveness of this unique mounting in absorbing the hardest jolts and jars, and thus protecting the glass tube from breakage, has been demonstrated. A completely assembled instrument was repeatedly dropped in all positions from a height of 4 feet on to a hard floor, without injury to the tube in any instance. . . . . it can easily be imagined what would have been the effect on a cemented or otherwise rigidly mounted tube. . . . . The almost complete elimination of glass breakage, and the simple means for making a repair in the rare case in which breakage does occur, removes a most exasperating difficulty heretofore experienced with mercurial sphygmomanometers. . . .
> The design of the instrument shown (made by the W. A. Baum Company, New York) was developed along the lines of maximum service and convenience to the user, without the sacrifice of simplicity and ruggedness, which experience has shown to be so desirable in instruments of this character.

That is why the Baumanometer is guaranteed against glass breakage; and why no other instrument is so guaranteed at all—much less for the user's *lifetime!*

That is why we can assure you of perfect, uninterrupted bloodpressure service for your lifetime... *You couldn't expect more, —don't be satisfied with less.*

STANDARD FOR BLOODPRESSURE

Obtainable from all dealers or from the British Distributors:

HAWKSLEY & SONS, Ltd., 83 Wigmore St., London, W. 1

FOR INTERNAL TREATMENT OF
GONORRHŒA, URETHRITIS AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected ripe Sandal-Wood, the oil is bland and remarkably
FREE FROM THE IRRITANT AND NAUSEATING EFFECTS
which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Generale, 8, Rue Vivienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World

U.K. Agents: WILCOX, JOZEAU & Co., 15, Gt. St. Andrew St., W.C.2.

"CHAMPAGNE OF ENGLAND"

Gaymer's CYDER

GAYMER'S WAS FIRST SHOWN AT THE BRITISH MEDICAL ASSOCIATION EXHIBITION OF 1898.

WM. GAYMER & SON, LTD., ATTLEBOROUGH, NORFOLK

Prescribed in numerous cases *of nervous and heart disorders, also rheumatic conditions, etc.*

The active substances of the extracts from cone-bearing pine trees (Pinus silvestris, Abies alba, Pinus montana) is found in an oily substance commonly known as pine oil.

Novopine Sparkling Pine Bath Tablets contain this oil in a convenient form and an effervescence is introduced to facilitate successful solution in the bath. Their therapeutic value lies in their action on skin, lungs, and heart. For, in addition to the direct action through the pores of the skin, the ozonic aroma given off is automatically inhaled during the taking of a hot bath.

Besides their general cleansing and health-giving properties, they have been found especially beneficial as a remedy against nervous heart diseases and kindred disorders.

Samples on request from Natural Products Ltd., 40, Furnival Street, E.C.4.

Novopine
Sparkling Pine Bath Tablets

SULPHAQUA

LARGELY AND SUCCESSFULLY PRESCRIBED IN

Skin Diseases, Rheumatism, Gout, Neurasthenic : : Conditions in Arthritic Subjects, Etc. : :

And as a valuable addition to the Inunction TREATMENT OF SYPHILIS with Mercury.

Employed in BATH and TOILET BASIN.

Possesses powerful Antiseptic, Antiparasitic, and Antalgic properties. Relieves intense Itching and Pain, is WITHOUT OBJECTIONABLE ODOUR, and does not blacken the bath enamel. Recommended for the Skin and Hair. Especially useful in the treatment of Acne and Seborrhœa of the Scalp. Largely used in dermatological practice.

SULPHAQUA SOAP.

In Boxes of ½-doz. and 1-doz. BATH CHARGES, 2-doz. TOILET CHARGES, and ½-doz. SOAP TABLETS.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.

Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

Intestinal Disinfection

ALIMENTARY TOXÆMIAS

PUTREFACTIVE bacteria increase in numbers in the intestine as age advances. They are relatively scanty in the young child, but after middle life are usually present in considerable numbers. Of the micro-organisms concerned, proteolytic anærobes are probably the most important.

In individuals with a normal intestine and free evacuations, they may do little harm, but in those subject to intestinal catarrh, these putrefactive bacteria become more numerous and active, their products are formed in greater quantity and are more freely absorbed, and the condition of alimentary toxæmia results. The manifestations of this state are very protean, *e.g.*, "rheumatic" conditions, digestive upset, neurasthenia and neuralgias, increased blood pressure and its complications, and many others. The treatment, in the first place, obviously should be *intestinal disinfection*. For this purpose nothing surpasses the use of KEROL CAPSULES. They have solved for years the question of disinfection of the alimentary tract. They definitely reduce the bacterial content of the intestine, as shown by the reduction in *B. coli* by 99% when the capsules are regularly administered for a period of from seven to ten days.

We have from time to time published several booklets containing clinical evidence as to their value, and these we will gladly forward, on receipt of a postcard, to any member of the Medical Profession.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.

Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

WRIGHT'S LYSOL

BRITISH MADE :: :: BRITISH OWNED

When prescribing Lysol Emphasise "WRIGHT'S"

Wright's Lysol is non-irritant, non-caustic, and does not sting or roughen the most delicate skin. Safe to use—and certain in action.

The danger of so-called Lysols sold at ridiculous prices cannot be over-emphasized. Always prescribe "Wright's" Lysol; there is certain protection in that name.

British owned and British made by the makers of the world famed Wright's Coal Tar Soap.

Preferred by leading Hospitals.

A handy graduated measure is provided with every bottle.

BOWEL INFECTION
and
Pyorrhœa Alveolaris

"In the treatment of pyorrhœa alveolaris, unless intestinal sepsis is treated at the same time, and *overcome*, no local treatment of the dentist is more than palliative. May 31st, 1924. ———, L.D.S.; R.C.S."

"Nothing is more wanted in medicine than a reliable bactericide for the alimentary canal." May 1922, p. 313. "THE PRACTITIONER."

THIS WANT HAS AT LAST BEEN MET

"The most scientific method of treatment must obviously be the sterilisation of the putrefactive organisms in the intestines.

By the introduction of the new benzene derivative dimethylomethoxyphenol[1] the putrefactive organisms are destroyed and the B. coli, owing to their 'greater powers of resistance,'[2] under the changed environment are enabled to cast off their pathogenic virulence and resume their normal character. The significance of this addition to our therapeutic resources suggests the beginning of a new era in the treatment of disease; the fact that the poison trap of the intestines can now be brought under control may prove to be the solution of more than one hitherto undetermined pathological problem." "THE LANCET," 1923, i., 696.

[1] Now known by the convenient name "Dimol." [2] "The Lancet," 1921, i., 753.

THE EFFICIENCY of Dimol in the treatment of many other intestinal conditions of bacterial origin is conclusively told in the interesting clinical reports which, together with a brochure dealing with the pathological significance of the intestinal toxæmias, will be sent to any physician on application to the

Dimol Laboratories, Limited, 40, Ludgate Hill, London, E.C.4

Distributing Agents:

SANGERS, LTD., 258, EUSTON ROAD, LONDON, N.W.1.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.

May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.

It cannot harm the most delicate constitution and is at all times a safe and effective aperient.

ALOCOL

Colloidal Hydroxide of Aluminium

For Chronic Irritations of the Gastric Mucosa

WHEN alkaline therapy is indicated "Alocol" is the preferred form of treatment. Its advantages over the usual oxides and alkalis are manifest. Whilst the preparations in common use give momentary relief to painful symptoms they aggravate the morbid condition. Consequently such remedies are contraindicated, especially in stubborn, chronic cases.

The action of "Alocol" is superior in every way, because it does not merely confine itself to combating the symptoms of the trouble, but attacks the origin itself.

"Alocol" fixes the acid, not by neutralization, but by adsorption. It relieves pain, is slightly astringent, and limits the acid secretions. "Alocol" is always well borne; no harmful secondary action follows its administration, and its therapeutic effect is not diminished with prolonged use.

Complete chemical history of "Alocol," with convincing clinical reports and supply for trial, sent free to physicians on request.

Analysis of the Cresylic Acid Content of Lysolats

There is no need to remind Medical Men that the Lysols on the market represent varying grades of cresylic acid, many containing a high percentage of impurities which attack and irritate the tissues. For the information of doctors who insist upon the highest grade of cresylic acid, the makers of Lysolats wish to make known the following analysis of the cresylic acid content of their solid form of lysol.

Composition. 99-100 per cent. (A mixture of 50 per cent. Meta-Cresol, 25 per cent. Para-Cresol, 25 per cent. Ortho-Cresol, with small quantities of Homologues.) Impurities do not exceed 0.1 per cent., including water, as follows:—

Pyridine, 0.05 per cent. maximum.
Naphthalene, 0.05 per cent. ,,
Light oil, nil.

Specific Gravity. 1.040 to 1.047 at 15.5° Cent.

Boiling Point. Not less than 90 per cent. distills between 195° and 205° Cent.

Odour. Pleasant. Clean and free from sulphuretted hydrogen.

Solubility in Caustic Soda. 10 c.c. dissolved in 40 c.c. of caustic soda solution (of a specific gravity of 1.060) gives a clear solution.

Members of the Medical Profession are invited to write for free samples of Lysolats to Solidol Chemical Ltd., Ashmead House, Disney Street, London, S.E.1.

Anæsthetic Ether

Nearly five years ago, in the course of the research on the purity of ether carried out in the laboratories of The British Drug Houses Limited, it was discovered that ether made from methylated spirit could not be purified by any means to that stage of high purity which was held by the B.D.H. to be necessary for obtaining anæsthesia under the safest and best conditions. In due course, after laying full scientific data on this subject before the Government chemist, The British Drug Houses Limited were granted permission to make ether from alcohol to which no methylating agent had been added.

The ether thus manufactured was introduced to the profession some three years ago under the name AETHER PURISS. B.D.H., and throughout its history this ether has been manufactured entirely from duty-free spirit; further, it is packed under controlled conditions which can ensure its arrival in the operating theatre in its original pure condition.

The extreme purity of Aether Puriss. B.D.H. has led to its adoption in a large proportion of the more important hospitals throughout the country.

INSULIN "A.B."

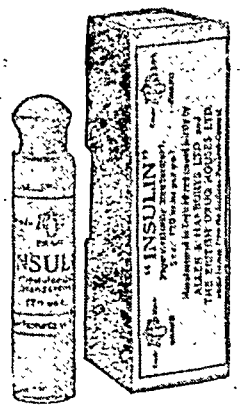
TRADE A B MARK Brand

"A.B." Insulin was the first British Insulin available for use by the Medical Profession and after almost five years retains its reputation as the Insulin which can be relied on to give consistently satisfactory results. The supremacy of "A.B." Insulin is due entirely to the stringently high standards of purity, therapeutic efficiency and stability self-imposed by its manufacturers.

"A.B." Insulin connotes:

Uniformity of unitage.
Full potency and stability in all climates.
Purity and complete sterility.
Absence of reaction-producing proteins with consequent noteworthy freedom from unpleasant-by-effects.

The activity of "A.B." Insulin is guaranteed by the most complete physiological tests and standardisation on the basis of the accepted unit. Before issue, each batch is passed under the authority of the Medical Research Council.



Supplied in two strengths:

20 units per c.c.

Packed in bottles containing:

5 c.c. (100 units or 10 doses) 2/8 each

'I PRESCRIBED BEMAX IN CASES OF MALNUTRITION'

D. 76. I prescribed Bemax in cases of malnutrition and angina. There was an improvement in weight and general tone, the heart is stronger and the angina pains are less frequent. M.B., B.S.

D. 66. I prescribed Bemax for a patient of mine with malnutrition due to old age and she was able to retain this food when she was unable to retain any other and showed improvement. M.B., B.Ch.

Bemax is now established as the B vitamin food. Over 27,000 members of the medical profession are taking Bemax themselves or prescribing it for their patients, with excellent results. The diseases for which medical men are prescribing Bemax are Constipation, Intestinal Toxaemia, Debility, Neurasthenia, Rheumatism, Gastric disturbances and all forms of skin disease. In fact, any ailment due to B-vitamin deficiency. If you have not tried Bemax, a free full size tin will be sent you on receipt of your professional card.

Regesan

CREAM OF MAGNESIA WITH LIQUID PARAFFIN

(Contains 30% Liquid Paraffin)

A stable, well-balanced combination containing 30% Liquid Paraffin held in suspension in a finely divided state. Its consistency is such that the tendency to leak exhibited by *Liquid Paraffin is eliminated.*

Regesan Cream of Magnesia with Liquid Paraffin provides suitable treatment for all digestive troubles with which constipation and hæmorrhoids are associated. It is certainly the ideal laxative during pregnancy and lactation, and most suitable for infants and children.

CATARRH

Its Prevention and Relief

Mistol, applied with a Mistol Dropper in the nose, is extensively prescribed by nose and throat specialists to prevent the recurring attacks of catarrh, and also to aid in the relief of acute paroxysms resulting from this ailment. Being an oily preparation, Mistol diffuses and spreads itself in a thin film over all parts of the mucous membranes of the nose and throat. It clings tenaciously to mucous membranes, and is not easily washed away by the natural secretions. Thus it affords relief in all inflamed and irritated conditions, and assists in warding off infection.

Sold in original sealed cartons containing a—

Mistol
(Registered Trade Mark)

Two-ounce Bottle and Mistol Dropper.

B

The Complete Antiseptic

Monsol differs radically from all other antiseptics on the market. It attacks *all* germs, whether surface or deep seated, without irritation or injury to the most delicate tissue. Such is its great germicidal power that its effect on the germs responsible for sepsis is ten times greater than that of pure phenol or lysol. Yet it can be applied in effective dilution even to mucous membranes without the slightest risk.

These powerful germicidal properties are possessed by each one of the Monsol products making them the most effective yet produced.

'BYNIN' AMARA

(TRADE MARK)

A Powerful Tonic and Hæmatinic

'Bynin' Amara is of special value in influenzal conditions and in the marked asthenia and nervous depression which are prominent features of the post-influenzal state. A course of 'Bynin' Amara whenever there is any indication of lowered resistance is a valuable safeguard against infection.

It has important advantages over Easton's Syrup on account of its basis being 'Bynin' Liquid Malt in the place of syrup. The 'Bynin' Liquid Malt, besides having valuable digestive and nutritive qualities is an efficient solvent for the other ingredients and helps to mask their unpleasant taste.

In bottles at 3/6, 6/6 and 12/-

INSCRIPTION IN WHICH ASOKA PROCLAIMS HIS INSTITUTION OF A SYSTEM OF STATE MEDICINE AND THE DISPATCH OF MEDICAL MISSIONS TO CEYLON AND VARIOUS KINGDOMS OF SOUTHERN INDIA.—Asoka himself no doubt studied medicine at the ancient Indian University at Taksha-sila (Tascila), which included a renowned medical school. The inscription here reproduced shows how he extended the pioneer work of healing, for which his predecessors had already founded institutions. It reads: "Everywhere in the realm of His Sacred and Gracious Majesty the King, and likewise also in the border lands, such as the countries of the Cholas, the Pandyas, Satirjaputra, Keralaputra, as far as Ceylon, of Antiochus the Greek king, or the kings in the neighbourhood of that Antiochus—everywhere has His Majesty the King made healing arrangements for men and healing arrangements for animals. Medicinal herbs also, both for men and for animals, wheresoever lacking, have been everywhere both imported and planted. Roots also and fruits, wheresoever lacking, have been everywhere imported and planted. On the roads, too, wells have been dug and trees planted for the enjoyment of men and animals.' The word translated "healing arrangements" is not an exact word for "hospitals" but it includes this meaning. The medical school of Tascila played a very important part in the spread (7th to 11th centuries A.D.), of Hindu medicine to Europe, through the Arabs who brought Hindu physicians to Baghdad to institute and organise hospitals and medical schools, and who sent their students to India for the study of medicine.

A British Medical Association Lecture

ON

SEDATIVES IN LABOUR, PARTICULARLY "TWILIGHT SLEEP."

DELIVERED BEFORE THE LEICESTER AND RUTLAND DIVISION

BY

JOHN S. FAIRBAIRN, M.A., B.M.OXON., F.R.C.P., F.R.C.S.,

CONSULTING OBSTETRIC PHYSICIAN, ST. THOMAS'S HOSPITAL, LONDON.

SOME preliminary observations are necessary to emphasize the important part played by sedatives in modern obstetric practice by removing influences inhibiting uterine action.

The chief characteristic of present-day midwifery as compared with that of a generation ago is its permeation with the ideals of preventive medicine, with the preservation of normal function in all systems of the body, as its primary aim. In midwifery our aim must likewise be to secure the normal throughout the processes of reproduction, in pregnancy, labour, lying-in, and lactation, and all interference with or substitution for normal function must be regarded as a failure to attain that end. In accordance with this principle success in obstetric practice will be measured by the proportion of natural pregnancies and labours obtained without disability in mother or child.

Suppose that by careful ante-natal supervision the various discoverable causes of disordered function in labour have, so far as possible, been eliminated—the misfits, malpresentations, malpositions, and such-like—and the physically well-developed and healthy woman, in whom no abnormality, general or obstetric, is found, is alone under consideration, can we be certain that she will have a normal labour and deliver herself without artificial aid? We cannot, and why? Because there may be some failure of the natural powers—particularly of the final expulsive powers—usually the failure to overcome the last obstacle to the birth, the resistance of the muscular pillars at the outlet. Hence the frequency of the low forceps operation, particularly in young and healthy primiparae, in whom fatigue is readily produced by the longer labour. The failure here is generally ascribed to the resistance of the soft parts—a factor undoubtedly—but, with the uterus working strongly and good expulsive efforts, the soft parts would give; in other words, relative weakness of the expulsive powers occurs. No hard-working, self-respecting uterus will be checked for long by soft parts. The failure of function is the non-development of the strong final contractions that are normally excited by the distension of the vagina and outlet.

The possible causes of even these minor failures to complete natural parturition and how they may be removed or circumvented must be thought out by all who approach midwifery in the proper attitude of mind. Those who continue without further thought to fall back on a substitute for the natural powers are living in the mechanical era (of which more anon) and are not imbued with modern ideas. Commonly the reasons are fatigue and weariness of the patient together with the inhibiting effects on uterine action of mental states, such as fear and anxiety, and the elimination of these inhibiting influences by sedatives is an important part of the management of labour.

FREQUENCY OF ARTIFICIAL AID.

Why has assistance in labour become so common that it has been stated that parturition is "pathologic" rather than "physiologic" in the women of to-day? Artificial delivery is more frequent among the more educated and leisured classes. The woman inured to hardship delivers herself easily and is up and about in a short time, for she can submit to conditions impossible to her more imaginative and sensitive sisters. Why are the women, especially of the more leisured classes, to-day less capable of reproducing their species than their great-grandmothers, in whose days forceps delivery occurred in but a fraction of the cases in which it is now practised?

The attitude of the medical profession has undoubtedly played an important part, for medicine as a whole, and obstetrics with it, has passed through a phase in which substitutes for nature have been developed and perfected—for example, the strong biceps of the accoucheur instead of the uterine muscle, artificial feeding instead of breast-feeding, and the excessive resort to Caesarean section. Also the relief of pain is expected from childhood onwards, for the extraction of a tooth or other minor surgical procedure, and women to-day feel the right to expect from their doctors the relief in labour that chloroform and the forceps can give. Many practitioners, indeed, advocate what they term the "humanitarian" indication for forceps delivery, and it is on that ground that the one who acknowledged to a forceps rate of 100 per cent., "if I am there in time," could be justified. Certainly the rate is five or six times greater in family than in hospital practice. There has thus come about a change in the mental attitude of the women themselves; they are not prepared to do without the artificial relief that the doctor can give, and have not confidence enough in their unaided efforts, and, in the conditions in which family practice is conducted, the pressure on the doctor to give his aid is often too strong to be resisted.

MAINTENANCE OF NATURAL FUNCTION.

Although the securing of natural function in parturition is a more difficult problem than it was, our object must be to find an answer to the question, How can we circumvent the social and psychical changes that have come with advances in medicine and with the changed attitude of mind in which the reproductive function is approached by the women of to-day?

The problem may be stated in terms of the physiology of labour. There are certain factors that augment uterine action—for example, the reflex effects of the dilatation of the cervix, the distension of the vagina, and the stretching of the perineum by the foetal head; and certain inhibitory factors—distension of bladder and bowel, fatigue and emotional states, together with the loss of the augmenting effects by the diminished reflex response that comes with anaesthesia and other means of lessening sensitiveness to pain. The question thus resolves itself into considering how far the good results of anaesthesia, analgesia, and sedatives generally can be obtained with the least loss of augmentor reflex response. Further, it must be our object to lessen pain and distress and avoid the more protracted recovery that may follow any severe nervous strain.

Recognizing that the factors mentioned are largely psychical, something can be done by educating the pregnant woman, and encouraging her to regard herself as better able to perform a natural function than her granddam, and as well able as the hardier woman of the working classes; also by explaining what she has to do herself and when she can get relief. Every one of us must acknowledge the value of the first-class midwife in keeping up her patient's confidence and encouraging her to make the most of her own powers. Something can be done in ante-natal and intra-natal management in this direction.

SEDATIVES.

To come to our subject, the use of sedatives. You all use them to some extent, and it does not matter in what form, but my own preference is for morphine, occasionally combined with a sleeping draught, such as a bromide and chloral mixture. A sedative may be indicated early in labour when the onset of the true rhythmic pains is delayed, and the woman is worried and fatigued by short, sharp pains that appear to do no good, or by a period, perhaps a day or more, of "niggling" pains, before the long, steady, and useful contractions are established. Also when the patient is tiring any time before the os is fully dilated and the head low in the pelvis. If she is left alone she may lose self-control, weep and throw herself about, and later become played out, and her uterus will not function properly. A hypodermic injection of morphine should be given when she is tiring, and before she is tired; the rest and comparative relief will enable her to regain her self-control, and uterine action will return with fresh strength after a period of rest. The relief to the patient also brings relief from the insistent pressure of distracted relatives that is so trying in domiciliary midwifery.

Punch, always a keen critic of the frailties of the day, hit it off in that delightful picture of the doctor assuring the prospective and overwrought father that in all his midwifery experience he had not yet lost a father.

Another indication for the use of a sedative is what is called rigidity of the os. Commonly it is spasmodic, organic rigidity being very rare, and is most often met with in nervous, highly strung, but perfectly healthy primiparae. This rigidity is not to be considered as a specific condition of the cervix, for it is merely the expression of poor or erratic uterine action; with good contractions there will be good dilatation, with poor contractions poor dilatation. Rigidity frequently accompanies the cases already described in which the pains are short and sharp and without rhythm, sometimes termed "colicky" action. The rigid os is to be regarded as a sign of disordered uterine action, and of the kind that yields to an opiate or other sedative.

Whenever there are signs of commencing fatigue, loss of control, and irregular uterine action, a liberal dose of some sedative should be given and repeated if need be. Practically all our emergency cases of delayed labour sent into hospital for immediate delivery—in many of which premature efforts at instrumental delivery have been made—are given morphine (1/4 or 1/3 grain), and it is surprising how many of those without gross mechanical difficulties will deliver themselves after four or five hours' sleep—and sometimes catch us out by performing an unlooked-for "B.B.A." My experience of this type of case in hospital and of cases seen outside that take on a fresh aspect after a few hours' sleep has made me feel that enough use is not made of a sedative sufficient to secure for the patient a rest before resort is made to artificial delivery. If the head is near the outlet it is too late to secure rest, and simpler to try first an injection of pituitrin as a stimulant to uterine action, and if not successful in a quarter of an hour to deliver by the forceps. Also, morphine at this stage is liable to result in the foetus being born narcotized.

Twilight Sleep.

The morphine-hyoscine narcosis, or "twilight sleep" (Gauss), must be regarded neither as an anaesthetic nor an analgesic, for its aim is the production of amnesia of the events throughout labour. Its success is complete if the mother awakes from sleep or drowsiness following her delivery without any recollection of what she has been through, and if neither she nor her infant shows any ill effect from the narcosis. Dulling of pain to some degree is usually obtained, but the real objective is to abolish the memory of the recurrent pains, and thereby their psychical effects. The patient may groan during uterine contractions, wake up and perhaps raise her head and shoulders from the bed, exhibit the facial expressions of pain, and even complain bitterly and emphatically, but will sink back into a recumbent position and drowsy state when the contraction passes off, and no mental impression that can be recalled will remain. The successful induction of amnesic narcosis removes almost entirely the inhibitions of uterine action of emotional and psychical origin, greatly lessens fatigue, and increases the chances of rapid recovery without the nervous exhaustion that may follow a painful and trying experience in a sensitive subject.

It may be said that labour in such circumstances is not physiological, and it is true to the extent that drugging of a patient in this way diminishes the reflex response to those stimuli augmenting the strength of the contractions; but, on the other hand, it represents the attempt to remove those factors interfering with good expulsive power that the circumstances of our modern social life have brought about. Its use will be justified if the cases in which the narcosis is adopted are limited to those in which the avoidance of fatigue and the exclusion of inhibitory factors will give greater benefit than the disadvantages of lessening reflex response.

Method.

It is best to begin as soon as rhythmical labour pains are definitely established and cause distress. Some would have a degree of dilatation of the os to a size admitting one or two fingers, but examinations for the purpose of determining the amount of dilatation are not advisable. As will be explained later, it is, however, nearly always possible to begin induction after labour has been in progress some time by starting with light chloroform anaesthesia.

It is very important that the usual preliminaries preparatory to labour, particularly a thorough emptying of the bowels, should be got over before induction of the narcosis is begun, in order to lessen disturbance of the patient. Isolation and quietude for the patient are essential, to exclude so far as possible all external stimuli. She should be shaded from the light, her ears plugged with wool, and disturbed as little as close watching of her condition and the necessary attentions will allow.

The dosage is best described by taking a standard one and suggesting modification in one or other direction in certain conditions. The usual initial dose is 1/4 grain of morphine with 1/150 grain of hyoscine, followed at hourly intervals by 1/450 grain of hyoscine. The morphine is rarely increased beyond 1/4 grain, and is repeated only in special circumstances and in smaller quantity, but the hyoscine may be increased to 1/100 grain for the initial dose, or more often to 1/300 grain for the second dose if the response to the usual initial dose is insufficient. The general rules for determining the best dosage in the individual case may be stated thus. The standard dose should be increased in first labours and for big women of strong physique, and for imaginative, oversensitive, and nervous patients. Morphine 1/6 grain and hyoscine 1/450 grain will suffice for multiparae, for women of a small or frail build, and for those of an easy-going unimaginative type. If begun early in labour, and the patient is a big, strong primigravida intolerant of pain, the first dose should be morphine 1/4 grain and hyoscine 1/100 grain, the frequency of the injections and dosage of hyoscine afterwards being determined by the effect obtained. Idiosyncrasy to hyoscine must be watched for, and the subsequent injections lessened if need be.

The standard time for the subsequent injections of hyoscine is, roughly, at hourly intervals, but in practice the frequency is determined by the effect produced, the memory test being adopted as an index of the amnesic state. The time of the second injection may be anticipated if the response to the first is feeble, but, generally speaking, it is better to keep to the 1/450 grain at shortened intervals rather than increase the amount to 1/300 grain, unless very little effect has been obtained from the first dose.

The memory test is carried out by taking some fairly common object that will not greatly tax the patient's muddled intelligence to recognize, showing it to her, and asking what it is. An hour or so later she may be roused, and asked what she was shown. If she has no recollection of it, the object is produced and the question repeated. If the object presented to her brings back no glimmer of its previous presentation, amnesia is complete. The test is not reliable; often women are able, by an effort at the time, to remember objects previously shown, but are found to have lost all memory of the events in the labour after it is over. Also repeated rousing for this purpose is an interruption to the narcotic state. The test should not be begun till after the second or third injection, and, so far as possible, should be carried out when the patient is disturbed for some other reason—for example, for a drink, a hypodermic injection, to pass water, or have a catheter passed. Also, if any attention of this kind of a sufficiently distinctive character is repeated, the opportunity can be taken to see if the memory of the previous occasion remains.

With further experience the need for repeating the hyoscine injections can be largely determined by noticing whether the patient is fully under the influence of the drug and by watching for signs of overdosage. When fully narcotized she should be drowsy, dosing between pains, but wakened up by them, and relapsing at once into drowsiness again. Should she show no evidence of disturbance during the pains no further injections should be given until some effect becomes noticeable. Usually, after the second or third injection, an interval of two or more hours may be allowed before the next one, provided quietness and drowsiness continue.

Flushing of the face and dilatation of the pupils are usually present early and are not necessarily indications of overdosage. The pulse and respiration rate should be

carefully observed, as any marked alteration either in the direction of slowing or quickening is an indication for ceasing administration for a time. With overdosage the pulse rate is *increased and the respiration rate slowed*, and therefore a watch should be kept on any disturbance of the ratio between the two. Usually there is at first some slowing of the pulse rate, probably from the previous excitement and subsequent quietude. When once the pulse rate has settled down, however, it should not alter greatly.

Unfortunately patients are very variable in their response to hyoscine; most of them conform to the type described - sleepy or drowsy between pains but roused by them. Some, however, may remain awake and yet be found afterwards to have complete amnesia, and others may become restless and troublesome. There is always considerable mental confusion, but unless it is associated with excitement and difficulty in controlling the patient, it is not an indication for interfering with the injections. Some degree of restlessness is usual in the early stage, before the complete effect of the drugs is obtained, but *in occasional instances it may become very troublesome.* It is an indication of overdosage with hyoscine, and may require further administration to be discontinued. A watch must be kept on the bladder, and if the patient is unable to empty it voluntarily the catheter must be passed. Thirst is always well marked and leads to frequent drinks being given. Food, usually liquid, must be given in all lengthy cases.

It will be clear from this general account of its administration that the amnesic narcosis calls for the continuous observation of the patient by a skilled nurse and constant attention by the practitioner in charge. The patient may appear quiet and yet wake up suddenly and, in her mental confusion, get up and wander about and do strange things—for example, hide herself or try to escape. No bowls of poisonous lotion should be left within easy reach, for thirst may drive her to sample the first fluid that comes to hand. Also to get good results calls for experience in the method.

There are *sundry modifications that make its partial* use easier to those with little experience of it. Its effects are most valuable in the first stage of labour. In the second stage when the stronger expulsive pains and the distension of the outlet are likely to rouse the patient, resulting in her reconstructing the whole labour and making the induction a failure, it is often easier to fall back on a light general anaesthesia, especially once the outlet begins to gape and birth is imminent. If that is done, it may not be "twilight sleep," but amnesia is secured. Also, if the injections have been discontinued or the patient is *out of control, chloroform* anaesthesia may be induced—just sufficient to allow of a full examination being made—and if the os is not fully dilated or the head not deep in the pelvic cavity, another injection of morphine—a small dose, say 1/8 grain—may be given which will take effect before the general anaesthesia is recovered from.

The great objection to the routine adoption of this form of narcosis in labour is, to my mind, its undoubted effect in lessening the expulsive contractions of the uterus and voluntary bearing-down efforts, and thereby increasing the number of low forceps operations. The effect on the child —which appears to be almost entirely due to morphine—is of minor moment, as, though born apnoeic and disinclined to breathe, if left alone respiration will be established in a short time. The injection of pituitrin 1/2 c.cm. (that is, up to 5 units) will reduce the number of forceps deliveries, but leave them still above the average, as we found when the method was tried out in a series of cases not specially selected as suitable. The effects on the third stage are not noticeable. Hence my view is that both a careful selection of cases should be made and strict adherence to Gauss's method left to those with long experience of it.

Selection of Cases.

It is valuable for all patients in whom a long and tedious labour may be anticipated, particularly cases of slight disproportion between the head and pelvis, when a long time for moulding is essential. Many of these cases would be of the kind designated as "trial" labours, and in them it is undoubtedly of great service in lessening fatigue; as soon as the head is well down further administration of hyoscine may be stopped and, if the patient *delivers herself*, a little chloroform given during the birth of the head. If delivery by forceps is required, anaesthesia is necessary. It is also useful in cardiac cases that have been under ante-natal treatment for decompensation, by lessening fatigue and strain during labour.

Apart from cases in which there is a cause or clear reason for avoiding fatigue, this method is adopted occasionally for cases in *which the temperament or excitable* state of the patient, especially if associated with a slow and erratic onset of labour, suggests it. It is often asked for by women who have either had a trying experience in a previous labour or have a great dread of what is before them and are without confidence in their unaided powers of going through it. It is always advisable in a medical school to select cases of this type now and then for instructional purposes, so as to keep nurses and students acquainted with the method.

SUMMARY.

Fatigue is of the mind as well as of the body, and is *hastened and aggravated by continued pain without relief*, by fear, and by loss of self-control, and is a potent factor in the production of inertia and other disorders of uterine *function.*

With experience on the part of doctors and nurses, success in obtaining amnesia will be attained in nearly *three-quarters of the cases, and some relief in the* remainder. A great saving of nervous strain is undoubtedly effected by this form of narcosis, but if carried through to the end it has the *fatal objection of increasing* intervention in labour. For that reason, save in a few special cases, such as I have indicated, I prefer to use morphine, *with or without a sleeping draught, or the single initial injection of morphine and hyoscine as and when it seems* to be required.

It will be clear that much patient study and observation is required before a solution is reached of the problem of how the relief of the pains of labour and the avoidance of fatigue and nervous strain can be secured without interfering with normal function. Much more must be done in exploring the causes of failure to complete a *natural function among physically well-formed women*, and so long as the artificial substitute of the forceps is acquiesced in, so long will obstetric practice fail to become *saturated with the principles of preventive medicine.*

EPIDEMIOLOGICAL OBSERVATIONS ON HOOKWORM INFECTION.

DISCUSSION OF THE QUESTION OF IMMUNITY AND SPECIFIC REACTIONS OF THE HOST IN HELMINTHIC INFECTION.*

BY

F. FÜLLEBORN, M.D., D.Sc.(HON.),

PROFESSOR AT THE UNIVERSITY OF HAMBURG AND THE INSTITUT FÜR SCHIFFS- UND TROPENKRANKHEITEN.

At the invitation of the Government of the Argentine, two years ago, I had, together with Dr. Roberto Dios and Juan Zuccarini, the opportunity of studying the hookworm question in the northern departments of the province of Corrientes, immediately adjacent to Paraguay. The Argentine is in general practically free from endemic hookworm infection, *although the frontier* between it and Paraguay are heavily infested with the worms, especially *Necator americanus.* According to Soper (1925) Necator seems to have *been introduced from* the north by African negroes; Paraguay was infested with the same parasite apparently only fifty to sixty years ago by Brazilian negro soldiers. *Ancylostoma duodenale* has apparently a much longer history in South and Central America, and either was brought over by the Spaniards or, as suggested by Soper (1927), is indigenous to the Indian race. In Paraguay and North Corrientes, however, only 5 to 6 per cent. of the expelled human hookworms belong to this species.

* Being a lecture delivered, under the auspices of the University of London, at the London School of Hygiene and Tropical Medicine on March 12th, 1929.

In the north of Corrientes we found not only that practically 100 per cent. of the rural population was infested with hookworms, but that egg count (by Stoll's method) revealed an unusually high degree of egg output, corresponding to an average of approximately 430 hookworms per person—so far as such estimates can be exact.

I cannot discuss here the details of our results. The most striking fact was that, in contrast to nearly all the other hookworm-infested countries, we found everywhere in North Corrientes an average egg production about two or three times as high in children and young adolescents of both sexes as in persons over the age of 20 (see Table I).

TABLE I.—*Average Output of Hookworm Eggs per gram of Mushy Stool per Person from 396 Inhabitants of North Corrientes.*

Ages (Years).	Males.		Females.		Total.	
	No.	Hookworm Eggs.	No.	Hookworm Eggs.	No.	Hookworm Eggs (Hookworms).
3 to 10	96	4,316	47	5,757	143	4,816 (ca. 330)
11 to 20 ...	127	5,949	48	9,350	175	6,885 (ca. 550)
21 to over 50 ...	47	1,965	31	2,437	78	2,152 (ca. 170)
3 to over 50 ...	270	4,637 (ca. 380)	126	6,313 (ca. 510)	396	5,206 (ca. 430)

The figures in brackets are rough estimates of the number of hookworms present.

Among the latter group we found no cases with more than approximately 800 hookworms, although they may occur occasionally (see Fig. 1). But, even if we omit the

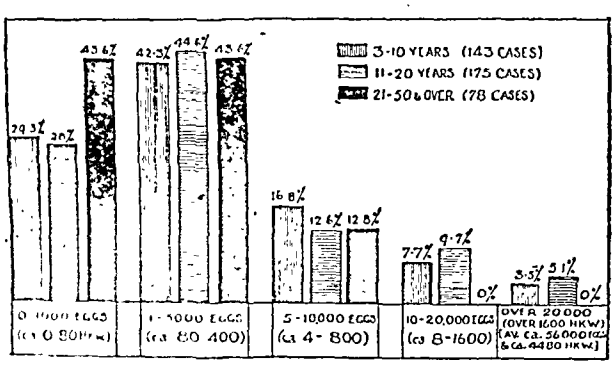

FIG. 1.—The same material as in Table I, arranged according to the output of hookworm eggs in relation to age groups.

unusually high infections with over 1,600 hookworms occurring in some of the young people, the degree of infection drops very decidedly after the twentieth year (see Fig. 2).

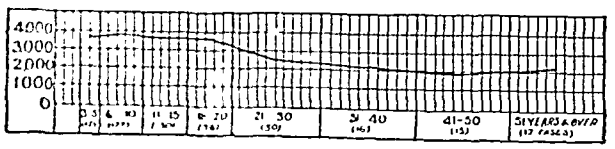

FIG. 2.—The same material, less 13 cases each with an output of more than 20,000 hookworm eggs per gram of faeces (equivalent to over 1,600 worms).

It may seem strange that, in contrast to our findings in Corrientes, the degree of infection among adults examined by Soper in Paraguay was three or four times as high as among children. The latter, however, were living under the hygienic conditions of a splendid orphan asylum, which precluded new infections, and we can corroborate the statements of Mhaskar and of Chandler that, under such conditions, the number of hookworms diminishes rapidly even in a few months. Indeed, when Soper was making his excellent and very careful examinations, he could not have known of Chandler's observations on this rapid "hookworm loss": observations which are absolutely in contrast to the previous statements of Smillie. If Chandler's observations are confirmed, many of the previous statistics will be practically useless in so far as they are based on the examination, not of the general population, but of prisoners, orphans, and so on.

While North Corrientes, like Paraguay, may be one of the most heavily hookworm-infested countries of the world, the clinical damage among the population is apparently much less in evidence than that reported from other Necator countries (such as Brazil) having a much lighter infection. This is probably because of the better standard of life, especially the better nutrition, of the Corrientes people (they consume a great deal of meat), which makes them more tolerant to their parasites than is the case with the Brazilian peasants, who, according to Smillie, are badly nourished and much overworked. That malaria, so frequent in many hookworm-infested countries, seems to be practically absent among the population of North Corrientes is doubtless another important factor in their favour, and perhaps the admixture of much Indian blood also increases their tolerance.

At any rate, the people of Corrientes in general give one the impression of being healthy, intelligent, and lively. In spite of their intense hookworm infection, their average haemoglobin rate, measured with the same individual instrument, was almost the same as among the healthy members of our institute at Hamburg, being 81.7 for the males and 74.6 for the females on the old scale of Sahli. Among the children and young adolescents of North Corrientes it is true there occur very heavy and even deadly cases of hookworm anaemia. On the other hand, only about 10 to 15 per cent. of the young people showed a loss of 10 units or more of the Sahli scale, the tolerance of the older ones being so remarkably high that the boys—but not the girls—between the ages of 10 and 20 could, without any average loss of haemoglobin, stand an infection with approximately 160 to 240 hookworms, although 100 Necator or less is considered in other countries as the limit. Moreover, the body size and weight of the school children corresponded closely to those of hookworm-free districts, such as Buenos Aires and Paris.

Surely, one can feel weak and miserable enough even without anaemia or any other objective symptoms of illness—a fact apparently also true of many hookworm cases. Nevertheless, one becomes more and more convinced, I think, that in the past the damage caused by a slight hookworm infection in native populations has often been overestimated, at least as far as Necator is concerned; *Ancylostoma duodenale* is doubtless by far the more dangerous parasite.

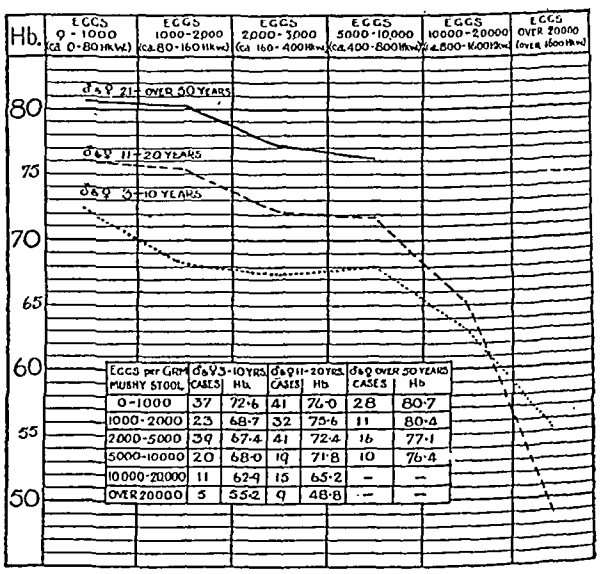

FIG. 3.—The average haemoglobin index (old Sahli scale) in 357 persons in North Corrientes, arranged according to the output of hookworm eggs.

Figure 3 shows in the vertical columns the haemoglobin value, according to the old Sahli scale (with about 80 for the normal blood of an adult); the horizontal divisions correspond to the "egg output," and therefore approximately to the number of hookworms present.

In contrast to the less tolerant children (up to 10 years), the adolescents from 11 to 20, as well as the adults, tolerate about 80 to 160 hookworms without an appreciable loss of haemoglobin. An egg production corresponding approximately to 160 to 400 hookworms is associated in all the age groups with an average haemoglobin loss of about 4 to 5 points; but it is remarkable that it is not higher in an infection with about 400 to 800 worms, the curve falling decidedly only above this limit.

The fact that the figures of Smillie from Brazil and of Carr from Mexico show the same tendency as found in Corrientes seems to justify the hypothesis, indicated by Smillie, that the host infected with a certain number of hookworms insufficient to overwhelm its resistance acquires the faculty of compensating in some way for the blood damage. Some of our preliminary experiments seemed to point to the formation of antibodies against haemolytic substances produced by the parasite.

As is well known, a haemolytic substance has been extracted from Ancylostoma by various workers; and my collaborator Dr. Kikuth found it several times in quite high concentration in the Ringer solution in which living *Ancylostoma caninum* had been kept at body temperature for some days, although for some unknown reason the haemolysin was not always present. The substance, not being destroyed by boiling, is apparently not of an albuminous nature; this fact, however (as will be discussed later), would not exclude our haemolysin from still acting as a "true antigen" producing antihaemolysin. But this possibility is apparently not realized, since the serum of our Ancylostoma dogs did not fix the haemolytic principle more than does normal blood serum. Moreover, the erythrocytes of the infected animals were destroyed by the haemolysin to the same degree as those of normal ones. Whether the haemolytic substance is active only *in vitro* remains to be investigated. However, according to de Langen and Djamil there is no evidence of chronic haemolysis in hookworm disease; apart from the intestinal bleedings there is apparently only toxic damage to the haemopoietic organs. If this view is correct, our haemoglobin curves from Corrientes, etc., would indicate only that the bone marrow can adapt itself, to a certain extent, to this chronic intoxication.

The literature concerning other specific helminthic products has increased so greatly that I can point out only some of the more important facts.

The precipitin reaction, and especially the complement-fixation test, are of some practical value for the diagnosis of Echinococcus and Bilharzia infections. Often the complement-fixation reaction is present also in patients harbouring *Ascaris lumbricoides*, and we found it positive in experimental animals repeatedly injected with Ringer's solution containing the products discharged *in vitro* by this parasite. The fact that after the removal of the Echinococcus cyst the complement-fixation test soon becomes negative, while, on the other hand, the "Casoni reaction" of the skin remains positive for a very long time (possibly for ever), seems to indicate that the two reactions are of a different nature, although they may be produced by the same worm products.

The active principle of the fluid from Echinococcus cysts causing the "Casoni reaction," like the antigen of other cutaneous reactions, is not of an albuminous or lipoid nature, because, as shown in 1926 by Lemaire and Thiodet, it passes through a dialysing membrane. According to the recent excellent paper of W. Jadassohn and our own experiments, this holds good also for the Ascaris substance, which provokes an itching urticaria-like swelling with an erythematous areola when put in superficial scarifications of a reacting skin. This substance, present not only in the body of Ascaris, but also in its secretions discharged *in vitro*, is absolutely stable against boiling. On the other hand, the volatile substances of Ascaris are unable to provoke such a skin reaction. As shown by Coventry and Taliaferro, and confirmed among others by W. Jadassohn and my collaborator Dr. Kikuth, the "Prausnitz-Kuestner reaction" is positive—that is to say, the sensitiveness is transferred with an intradermal injection of the serum from a reacting person to the injected area of the skin of a normal individual. Moreover, our experiments confirm Jadassohn's statements that the sensitizing property of this serum can be destroyed by adding a certain quantity of our thermostable Ascaris substance and that the latter becomes ineffective with the serum of a reacting person. In other words, the "antigen" and the "antibody" fix each other, and therefore, according to von Pirquet and others, the reaction is of the "allergic" type.

From the clinical point of view it will be advisable to suspect an Ascaris infection in cases of urticaria, and perhaps also in cases of asthma or other "anaphylactic symptoms," as will be discussed later. Furthermore, a Strongyloides infection is often associated with a peculiar type of urticarial eruption. In chronic infections with the parasite the skin can become so highly hypersensitive that even the extremely small quantity of "antigen" secreted by a single filariform larva can provoke an intense reaction; because, if a larva is wandering in the subcutaneous tissue of such a person, its way is marked by a quickly progressing urticarial streak. Spontaneous urticarial eruptions occur occasionally in nearly all my European cases chronically infected with Strongyloides; and these eruptions, being confined only to the buttocks and their vicinity, are of considerable diagnostic value. I think they are caused by filariform Strongyloides larvae developing in faecal particles, which even with apparent cleanliness can still adhere to the anus; it is clear that such larvae will enter the skin of these parts, which, in consequence of the repeated invasions, must become more and more "locally sensitized," as did the skin of my own forearm after many laboratory infections of my hand. The daily morning bath not being a sufficient prophylactic, washing must be repeated at least every evening; "Heliobrom-Teichgräber" mitigates the violent nocturnal itching. The constant reinfection with these larvae may contribute also to the remarkable persistency of a Strongyloides infection, lasting in one of my patients for twenty-six years; he has the honour, I think, of holding the "world record."

Although antigens provoking a more or less specific skin reaction may be present in every helminthic parasite the practical value of the method must not be overestimated. For example, we do not know how far a positive reaction to Ascaris antigen is specific in its nature; even if it were so, it would perhaps take some time for the skin of the host to become sensitized; on the other hand, the skin may stay sensitized long after the expulsion of the parasite, as shown by the Casoni reaction. Furthermore, one has to consider individual factors, and the skin of different races may not react in the same manner to helminthic antigens. It is important also in our test to take into account "group reactions." For example, the Strongyloides antigen is a very reliable diagnostic aid in chronic Strongyloides cases, and did not give a positive reaction if the person was infected only by Ascaris. On the other hand, the skin of Strongyloides carriers has reacted in my experiments not only to the Strongyloides antigen, but also to the antigen of Ascaris, and even to that of Trichinella, and of Echinococcus, although a former infection with the two latter parasites was very improbable.

At any rate, I think that at present the skin reaction has a practical value in helminthic diagnosis only for infections not easily detected in any other way. For the diagnosis of Echinococcus it is apparently superior to the complement-fixation test, and according to a recent publication of Fairley (1927) is very promising for the detection of Bilharzia; how the fallacy of the cutaneous method can be avoided in clinical use is also discussed in his valuable paper.

Instead of injecting worm extracts into the skin I prefer to introduce into a superficial scarification a trace of a powder prepared from the dried body of the parasite. This "Full-Antigen," as I call it in contrast to extracts, is very effective, can be kept for a long time, and is handy for clinical use. It may be advisable to heat the antigen powder to 100° C. to evaporate its volatile components, which are possibly associated with the "anaphylactic symptoms" that have in a few cases followed the skin reaction with Ascaris antigen.

As already discussed, the volatile substances of the Ascaris body, chemically determined so carefully by Flury, cannot provoke the skin reaction. Yet it is very difficult to understand how substances other than volatile can be involved in the frequent cases in which merely entering a laboratory where horse Ascaris has been dissected is sufficient to cause urticaria, erythema, asthma, and other anaphylactic symptoms. The same holds good, perhaps, for those cases in which the mere presence of a horse provokes

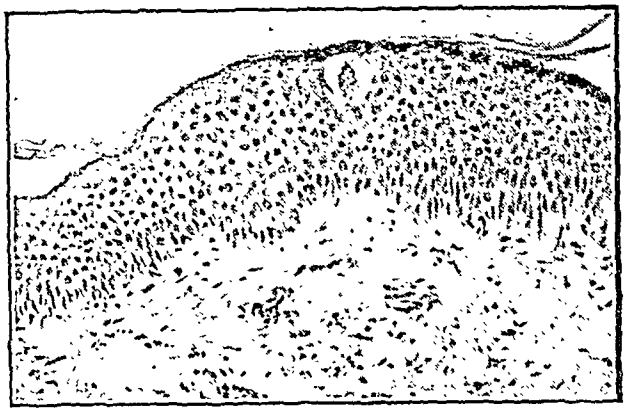

FIG. 4.—Section of skin with a larva of *Uncinaria stenocephala* under the stratum corneum. (Photograph × 150.)

such attacks. At any rate, our own experiments are not in favour of the assumption that in these cases the air may contain sprayed droplets of Ascaris fluid.

As found recently by Dr. Borchardt of our institute, some volatile aldehydes of the fatty acids (prepared in our laboratories by Dr. Oesterlin), which according to Flury are contained also in the body of Ascaris, produce in the cat a marked eosinophilia; on the other hand, the Ascaris tissue loses this faculty after boiling. We do not know if these volatile substances can provoke anaphylactic symptoms in experimental animals, but, at all events, eosinophilia is very closely associated with anaphylaxis. The erythema, urticaria, asthma, and other general symptoms, so often accompanying the perforation of the skin by the Guinea worm, and attributable, according to Fairley's classical investigations, to secretions discharged by the parasite, clinically resemble an anaphylactic shock. They, like other "allergic stages," are cut short promptly by adrenaline, as shown by Fairley. It would be interesting to try adrenaline in the Calabar swellings of *Filaria loa* infection, in which the very high eosinophilia is, I think, suggestive of an "allergic" nature. It is remarkable that the symptoms of anaphylactic shock occur not only after the rupture of an Echinococcus cyst, but, according to W. Jadassohn, even after merely touching the scratched skin with body fluid of the horse Ascaris. Further, according to Kellaway, a general narcosis not only prevents the anaphylactic shock in Echinococcus patients, but often inhibits also the development of the Casoni reaction—an observation suggesting that the skin reaction may be controlled by the nervous system. (The same seemed to be the case in our experiments in which the cutaneous reaction was negative in an area of skin previously injected with adrenaline; but the exudation involved in blister formation after a burn with hot water equally failed on such a treated area.)

The eosinophilia, so characteristic of helminthic infections, may be connected with the defence of the host against the toxic worm products, but, according to Sandground, hardly with immunity against the parasite itself. Indeed, our knowledge about such an immunity in helminthic diseases is very scanty. The fact that when many parasites of the same species are present the individual worms do not attain their usual size—as in the liver infected by many *Clonorchis sinensis*—suggests that the metabolic products of a parasite can prevent the normal development of its companions. This may be one of the reasons why in some helminthic infections hyperparasitism

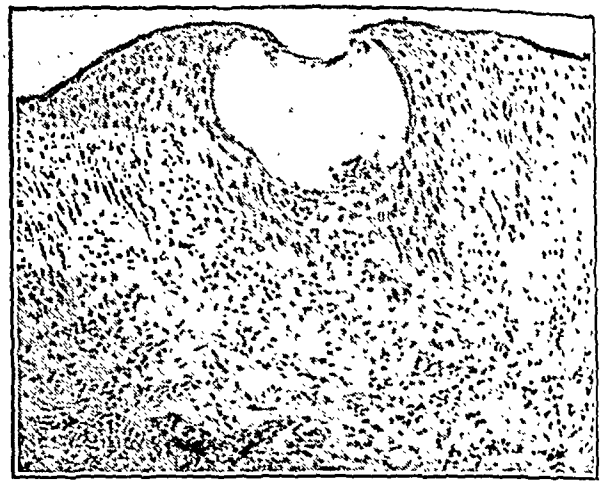

FIG. 5.—Section of the larval tract further backwards than Fig. 4 (Photograph × 150.) The pressure of the accumulating fluid has progressively enlarged the tract with flattening of the lining epithelial cells.

is possible only to a limited extent, as pointed out for *Filaria bancrofti* by Sir Patrick Manson, and found true also for *Taenia solium*, Schistosomum, and other parasites.

The immunity against hyperparasitism is comparable to a certain degree with the "*immunitas non sterilisans*" of Ehrlich, as seen in lues and other microparasitic infections; but the experiments of Gordon and Blacklock with the fly larva, *Cordylobia anthropophaga*, prove that in metazoan parasites also we have to consider an immunity persisting after the parasite's removal. The recent experiments of Sandground with *Strongyloides stercoralis* in the dog suggest that such a type of immunity can occur also in nematode infections, and I agree with Yokogawa that the very low susceptibility to *Toxocara canis* of dogs more than a year old is also a consequence of the prenatal infection of practically all our puppies, and not merely an "age resistance," as Martin has suggested in the case of swine Ascaris. But it is very difficult to exclude an "age resistance" in such cases, as is lately apparent from Herrick's experiments with hookworm larvae fed to dogs of different ages, although some of his experiments seem to indicate the presence of an "acquired immunity" in hookworm-infected dogs.

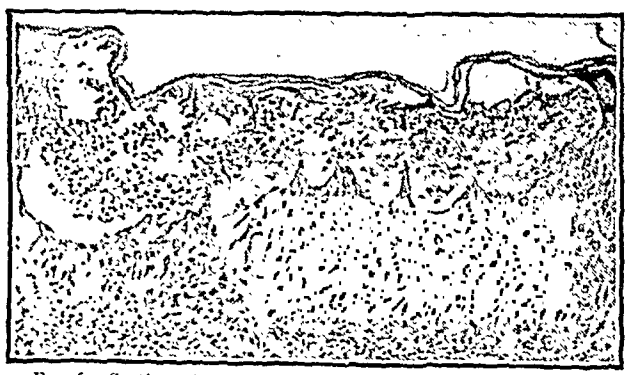

FIG. 6.—Section of another portion of the infected skin. (Photograph × 150.) Leucocytes progressing under the corneal layer; the continuity of the epithelial cells has been rent asunder by the tension of accumulating fluid.

According to Ohiro, by feeding with the parasite, immunity against *Toxocara canis* can be obtained in the dog. However, our similar experiments with *Ascaris lumbricoides* and rabbits were not conclusive, and Martin reports that his experiments with Ascaris extracts injected into pigs were negative.

The experiments of Hiraishi, who succeeded in infecting his pigs with human Ascaris only when their food did not contain vitamin A, suggests that deficient nutrition may diminish the host's natural resistance against the parasites. These findings are in accordance with recent experiments by Sollazzo in Claus Schilling's laboratory, which indicate that the natural resistance of pigeons against *Trypanosoma brucei* can be broken down by deficiency of vitamin B or by starvation. Moreover, one of my dogs, apparently immune to hookworms after repeated infections, became susceptible again when deprived of vitamin A; but, of course, such a single experiment cannot be considered conclusive.

The suggestion that the blood serum may be involved in the protection of the host against the parasite could be demonstrated neither in the case of Cordylobia immunity nor, according to Sandground, in the acquired immunity of the dog against Strongyloides; while in my own experiments the filariform Strongyloides larvae were agglomerated by normal as well as by specific serum. A "local tissue immunity" in Besredka's sense is apparently present in the skin previously infested by Cordylobia; possibly it is also found in the tissue of the intestine protecting it against parasites entering the mucosa (as Strongyloides does), and according to Holppli also feeding on its tissue (as hookworms do, or Ascaris and related forms). But the experiments of Herrick and Allen Scott, showing that a certain percentage of hookworm larvae in dogs do not even begin to feed on the tissue, but remain undeveloped for a long time in the intestine, are not in favour of this assumption. In addition, the bile secretion may have a "specific" influence, and some observations suggest that parasites can react to volatile substances. These are so highly characteristic for every species that the dog, for example, can distinguish by means of them not only the species, but actually the individual.

On the other hand, the experiments of Steiner and others with plant nematodes, and the behaviour of the various Strongyloides strains, tend to show that a parasite can adapt itself to the biochemical conditions of a new host; that such an adaptation precedes morphological changes is evident, the Ascaris of the man and the morphologically identical form in the pig being a suggestive example. But in spite of the fact that the biochemical processes of host and parasite seem to influence each other in many ways, there is so far no evidence of the production by the parasite of "antiferments" against the peptic ferments of the host. In any case, the Ascaris experiments of Weinland do not constitute such evidence, since, according to F. Einstein, Ascaris is protected against digestion by the impermeability of its cuticle.

Finally, some further remarks on hookworm epidemiology. As the "age resistance" to hookworm infection is so pronounced in dogs, one might expect the human child to be more liable than the adult. In nearly all the hookworm countries, however, the percentage of infected children is much lower than that of the adults. But the defaecation habits of primitively living people have such a decisive influence in hookworm epidemiology that the relatively low infection of the children may be merely a consequence of the use of defaecation places less contaminated with excrement (and therefore with infected larvae) than are the places frequented by the adults. As it is practically impossible to decide to what extent such habits may influence the hookworm statistics in different countries, we must be very careful in drawing general conclusions from any given material. Therefore the following deductions may, perhaps, not be conclusive.

So far as I know, apart from North Corrientes, an infection of young people higher than that of adults has been reported only from Mexico, by Carr, and from the rural population of Alabama, by Smillie and Augustine. In Alabama, however, the hookworm diminution after the fourteenth year of life is explained by the fact that shoes are used only after this age; in North Corrientes and Mexico, however, such differences between the habits of younger people and adults were not noted.

It is quite remarkable that just in North Corrientes and Mexico (*where, in contrast to the other hookworm* countries, the infection spontaneously decreases in the adults) the infection of the younger individuals reaches so high a degree as reported from nowhere else, a fact which suggests that the reduction of infection in the adults may be caused by an "acquired immunity" in consequence of the high and continuous infection during earlier life. Herrick points out that the epidemiological observations of Sawyer, Hill, and Dochter are also in favour of the assumption that, under the influence of a continuous hookworm infection, a certain degree of immunity against further infections is developed, especially when the former infection has been a high one. That the same seems to hold good for the hookworm-infected dog has already been noted.

The question of the varying susceptibility to hookworm infection in different races is of great economic importance. According to a very important paper by Smillie and Augustine, the *negro children in Alabama are much* less infected with Necator than are the children of the white farmers, and this in spite of the fact that they live practically under the same conditions. The authors suggest that since the epidermis of the negro children is thicker than that of the whites it is not so easily perforated by the hookworm larvae. The same, I think, may hold good perhaps for the skin of other coloured races. That the skin structure can influence the degree of hookworm infection is proved by the experiments of Looss and myself, which show that the tender skin of young individuals is more easily infected than is that of older persons.

Another clinical observation suggests a higher mechanical resistance of the negro epidermis against hookworm larvae than obtains in Europeans. Kirby-Smith, Dove, and White have described from Florida and its vicinity a type of "creeping eruption" clinically resembling the skin affection caused by the migration of a Gastrophilus larva. In the Florida cases, instead of a fly larva, the larva of *Ancylostoma brasiliense* of the dog was found in the epidermis. However, this species of hookworm larva may also find difficulties in boring into the negro skin, because the affection, although very common in the skin of whites, is practically absent in negroes.

About two and a half years ago the same affection developed on the forearm of an assistant and myself after some skin-penetration experiments with the larvae of the dog hookworm *Uncinaria stenocephala*. As this species is found also in European dogs, one has to consider the possibility of such skin infection in Europe. On the other hand, according to White and Dove in contrast to *Ancylostoma brasiliense*, the larva of *Ancylostoma caninum*, so common in most countries, is not involved in "creeping eruptions." This evidently is true also of the larvae of the human species. I have studied the normal course of the affection in my own skin, and although bacterial activity cannot be excluded, of course, I think that the essential cause of the peculiar pathological changes is a toxic secretion of the larva, small as this may be.

TUBERCULOSIS IN CHILDHOOD.*

BY

BERNARD SCHLESINGER, M.A., M.B., B.Ch., M.R.C.P.,

PHYSICIAN TO THE CHILDREN'S DEPARTMENT, ROYAL NORTHERN HOSPITAL; PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

THE high incidence of tuberculosis in childhood, its characteristic forms which differentiate it so markedly from the consumption of adults, the inevitable fatal prognosis of some types and, with correct treatment, the favourable outlook of others, make the subject of considerable interest and of the utmost importance. Reference to the Registrar-General's annual report for 1926 gives ample evidence of the frequency of tuberculosis in children. In that year tuberculosis was responsible for 8.3 per cent. of the total deaths in England and Wales, whilst 14.5 per cent. of all the deaths from tuberculosis occurred in children under the age of 15.

The susceptibility to the tubercle bacillus is not spread evenly over all the years of childhood. The disease is uncommon during the first eight months of life; but thereafter the liability to infection rapidly increases, reaching its height at the age of 2 years. From then onwards the body gradually acquires a certain degree of immunity. The lack of resistance to tubercle at an early age accounts for the marked difference of the life-history of the disease in children and in adults; in the young child it rapidly assumes a generalized and fatal form, whereas phthisis, the more characteristic adult type, is rarely seen in childhood. As the child grows older the lymphatic system comes to play a more important part. The lymphatic glands act as a powerful second line of

* A paper read to the North London Medical Society, March 8th, 1929.

defence, and are usually successful in holding up the infection. This leads to the second common form of the disease, glandular tuberculosis, which is much more frequently seen in childhood than in later life, when the function of the lymphatic system tends to be superseded by the whole defensive mechanism of the body.

When the bronchial or abdominal glands become tuberculous the disease may remain latent, and if left undisturbed it may finally heal. Meanwhile, however, these infected glands are a continuous menace, and are easily rendered active by some additional infection or lowering of the resistance. The infection then no longer remains confined to the glands, but spreads to neighbouring structures or bursts into the blood stream. Even in adult life the onset of consumption can often be traced to an original latent infection during childhood.

The Path of Infection.

Three varieties of tubercle bacilli are known—the human, the bovine, and the avian; the last of these, however, is so rarely the origin of infection that it need not concern us any further. Much has been written on the relative preponderance of human and bovine infections, but beyond indicating the nature of prophylactic measures, a differentiation is of no great practical value. Certainly there is no evidence that one is more virulent than the other. Whatever the relative proportions of the two varieties may be in tuberculous children, it has long been established that the infection is either acquired through drinking tuberculous cow's milk or through continuous close contact with an adult suffering from the disease—in other words, either by oral ingestion or by inhalation.

The exact route taken by the tubercle bacillus has been the subject of much discussion. Calmette believes that inhalation plays a small part, and that both in thoracic and in abdominal tuberculosis the bacilli enter through the mucous membrane of the throat or of the alimentary tract. This is in direct opposition to Ghon, who, by very careful microscopic examination, claims to be able to demonstrate a minute focus of tuberculosis in the lung in every case where corresponding caseous glands are found at the hilum. This minute lesion in the lung is thought to be the primary seat of invasion through inhalation. It is often so small that without a microscope it would certainly be missed, and in many cases healing has progressed so far that only a small scar remains.

Analogous primary foci of invasion are held to exist in the tonsils and the intestines, but in these situations also the lesion has become healed, or is so minute that its identification is often impossible and caseous enlargement of the glands draining these areas is the only obvious sign of tuberculosis. The disease may, in fact, spread back from such infected glands to the lungs and intestines, or ulcerate through into the general blood stream. In infancy the infection spreads easily to neighbouring organs, and is liable to take on the extremely fatal form of generalized septicaemia. In early childhood the glands become severely affected, and it is only when the barrier they form is broken down that adjacent structures are involved. Even then the disease may remain localized and recovery may follow.

Much has been done in England, by proper sterilization of milk and regular inspection of cattle, to eliminate the bovine source of infection, but the human source of infection is far more difficult to eradicate. Unless the utmost precautions are taken, a child brought up and nourished in tuberculous surroundings can hardly fail to become infected through his food, through kissing, or by inhalation of an atmosphere which must necessarily from time to time become charged with the germs.

Prophylaxis.

The surest way of stamping out the disease would be to remove all children of tuberculous parents from their homes to the country during the first year of life, but as in most cases this course is impracticable we are left with less satisfactory methods of prevention, of which the following are the most important. Tuberculous mothers should not breast-feed their infants, and the greatest care must be taken in the preparation of food so as not to contaminate it with unwashed hands, or by coughing or sneezing. The child's feeding utensils must be washed and kept apart from those of the rest of the household. The infected person must only spit into a special antiseptic receptacle, and must never kiss or breathe on the child. Windows must always be kept open; the child should be in the fresh air as much as possible, and should sleep on a balcony. If possible, the whole family should move to the country. The value of oral administration of attenuated live cultures of tubercle bacilli, as advocated by Calmette, has yet to be confirmed. Grade A tuberculin-tested cow's milk is guaranteed free from tuberculous infection, but if the milk supply is suspected, scalding, boiling, or pasteurization renders it safe.

Various tests have been devised to detect the presence of tuberculosis. The most valuable is the von Pirquet test, performed by the inoculation of Koch's old tuberculin into the scarified skin. This, when a tuberculous lesion is present, produces a circumscribed red wheal in about twenty-four to forty-eight hours. The Mantoux test is more reliable, but is virtually the same as the von Pirquet, except that the solution is injected intradermally. The test depends on the hypersensitiveness of the patient, or otherwise, to tubercle bacilli or their extracts. This allergic state is best seen in the skin, where a local reaction occurs as part of the body's defensive mechanism when these specific bacterial products are injected into people who have previously been sensitized to them. A mere passing tuberculous infection is sufficient to provoke this hypersensitiveness. It follows, therefore, that nearly all adults, and many children by the age of 10, will give positive Mantoux reactions, and the value of the test as an indication of activity is seriously limited. The reaction, furthermore, is positive whether the foci of infection are active, latent, or healed, and the test is therefore of greater diagnostic value in very young children, who are less likely to have old tuberculous lesions present. An additional disadvantage is that the reaction is often negative in the final stages of generalized tuberculosis and in tuberculous meningitis.

A hard-and-fast demarcation of the various forms in which the disease is found in childhood is not always possible; for instance, the association of hilum glands and abdominal tuberculosis is not uncommon, and any form may terminate in tuberculous meningitis.

Generalized Tuberculosis.

Generalized tuberculosis closely resembles ordinary marasmus, and is often difficult to recognize in infants. The temperature remains normal or subnormal, and only shows an irregular pyrexia a few weeks before death. In some cases vomiting is troublesome; in others, with extensive lesions in the lungs, there is persistent cough, rapid breathing, pallor, and generally cyanosis. A mild bronchitis is the only pulmonary sign, and the spleen is generally enlarged. Death results from progressive debility, lung disease, or meningitis.

In early childhood the manifestations are equally obscure and the symptoms generalized and indefinite. Peevishness, indigestion, loss of appetite, wasting, languor, and sleeplessness are the usual complaints; but the irregular pyrexia, marked pallor, and cachectic appearance of the child soon indicate a graver illness than the first mild symptoms suggested. Later, the occurrence of severe symptoms in the lungs, brain, or abdomen often helps to clear up the diagnosis. Generalized tuberculosis can be the cause of persistent high temperature for many weeks, and the diagnosis may present difficulty until meningitis appears as a terminal event.

The presence of an enlarged spleen or the discovery of other foci of tuberculous infection, such as tuberculous epididymitis and tuberculous dactylitis, is a great help in the diagnosis of such an obscure case. The discovery of small shotty glands at the outer border of the pectoralis major muscle on each side is sometimes an indication of tuberculosis when there is no other explanation of their presence. Ophthalmoscopic examination of the fundi should never be omitted, and the discovery of choroidal tubercle may often give the final clue. All these signs are, however,

often absent, and the child may finally die without the condition having been suspected. Once tuberculosis has become generalized no treatment is of any avail, and the patient can only be kept as comfortable as possible.

THORACIC TUBERCULOSIS.

Tuberculous Bronchitis.

Repeated mild attacks of bronchitis may be the earliest signs of tuberculosis, but since, clinically, they differ in no way from ordinary bronchitis, their true significance usually passes unnoticed. It is only when the disease is anticipated by reason of the child's tuberculous surroundings, or when on rare occasions tubercle bacilli are discovered in the sputum, that active treatment can be undertaken at this early stage.

Miliary Tuberculosis of the Lung.

When the infection reaches the blood stream multiple small tuberculous foci are formed in both lungs during the process of general dissemination throughout the body. Miliary tuberculosis is invariably fatal. At first the diagnosis may prove very puzzling, and the condition be taken for influenza or bronchitis, but the increasing pallor, progressive wasting, dyspnoea, and cough eventually give the clue. Irregular pyrexia, generally higher than in bronchitis or influenza, is present, and may remain for several weeks, leading to a suspicion of typhoid fever; enlargement of the spleen further enhances this similarity. An *x*-ray film of the chest is a great help in the diagnosis, and shows a general mottling of both lungs. Symptoms of tuberculosis elsewhere in the body may supervene, and the illness often terminates in meningitis.

Tuberculous Broncho-pneumonia.

This may arise without any previous pulmonary infection, but more frequently follows a simple broncho-pneumonia, particularly in association with measles or whooping-cough. This stirs up a latent tuberculous infection harmlessly situated in a caseous bronchial gland, and causes it to spread into a neighbouring bronchus. The illness generally terminates fatally in a few weeks, but may sometimes be prolonged for several months.

Tuberculosis is suspected in a case of broncho-pneumonia which fails to clear up after several weeks, the patient meanwhile becoming progressively emaciated, paler, and more languid. Persistent rapid breathing and irregular or continued pyrexia are additional indications. Temporary improvement is sometimes a striking feature, and may give rise to false hopes of recovery. Involvement of the pleura is common, and loculated serous effusions or small empyemata are formed. Examination of such pleural effusions may occasionally reveal the presence of tubercle bacilli, and these must also be sought for in the sputum. Children seldom expectorate, but sputum can often be obtained by touching the back of the throat with a piece of gauze wrapped round the end of a pair of forceps. A reflex cough is excited and the sputum is caught on the swab. Should these two examinations prove fruitless the search may be directed to the stools, or to a stomach wash-out for any tubercle bacilli that may have been swallowed. The discovery of chronic tuberculous lesions elsewhere may prove useful. The presence of opaque fluffy shadows in an *x*-ray picture of the lungs gives the deciding evidence. At times all methods of examination are inconclusive; the true nature of a persistent broncho-pneumonia with splenic enlargement, continued pyrexia, and progressive emaciation is then left in doubt, since the condition is quite compatible with either tuberculous or pneumococcal infection.

No treatment is likely to meet with success, but, in older children, in the rare event of the lesion being confined to one side, collapse of the affected lung by artificial pneumothorax may occasionally arrest the disease.

Pulmonary Phthisis.

Chronic consumption of the adult type is rare in children, and when it occurs the cavities often do not follow the same distribution as in adults, being principally situated near the hilum or at the base of the lungs. Haemoptysis is a rare event in an advanced stage of the disease, when tubercle bacilli may also be present in the sputum. A diagnosis of phthisis is undoubtedly too frequently made in children, areas of pulmonary fibrosis and unresolved pneumonia at a lung apex being wrongly interpreted as tuberculous. Such common symptoms of chronic indigestion as wasting, sweating, and evening rise of temperature may also cause confusion. Haemoptysis in childhood should never suggest tuberculosis. It is usually associated with adenoids or is a sign of advanced heart disease.

Tuberculosis of the Bronchial Glands.

The bronchial glands are more often the site of chronic tuberculous disease in childhood than any other region of the body. Children thus affected are not very ill, but are nevertheless potentially tuberculous. Minor maladies or debilitating diseases easily awaken this dormant tuberculous infection. It spreads back into the lungs, giving rise to serious consequences. The caseous contents of the glands may even burst directly into a bronchus or pass into the blood stream.

Such symptoms as arise from quiescent tuberculous bronchial glands are vague and indefinite. The child has a poor appetite and does not gain weight; his general development suffers, he loses his vigour, and becomes easily tired. The temperature is constantly a few degrees above normal and periodically may be considerably raised. There is a hoarse irritating cough, which is often paroxysmal in character and somewhat reminiscent of whooping-cough. It may, in fact, follow this infection without interruption, and the persistence of a spasmodic cough long after the whoop has disappeared points to the possible complication of enlarged bronchial glands. The glands may become so large in infants that their pressure on the trachea actually embarrasses the breathing, producing snuffles or stridor.

Several physical signs are said to be diagnostic of mediastinal glands, but in my experience they are all untrustworthy. It is true that submanubrial and paravertebral dullness may be present, but the glands need to be very large before either of these signs is elicited. D'Espine's sign and Eustace Smith's sign are of no great value since they can often be elicited in normal children. In every case a radiogram must be made, but even that will not show whether the glandular enlargement is due to tuberculous or to some simple catarrhal infection.

Prognosis and Treatment.

Immediately the condition is suspected and has been confirmed by *x*-ray examination and a positive Mantoux test, the child must be sent to the country or seaside, where he should remain continuously in the open air. Sun baths or irradiation with ultra-violet light, a nourishing diet, and tonics are also important items in the treatment. This must be continued until all symptoms have disappeared, the normal weight is restored, and the temperature remains normal. Septic tonsils require removal when the general condition has improved. Deep *x*-ray therapy in the hands of experts is sometimes strikingly successful in cases which are slow in reacting to other lines of treatment.

ABDOMINAL TUBERCULOSIS.

Tuberculosis confined to the abdomen is one of the commonest forms in children and is the most amenable to treatment. The infection is generally bovine through contaminated milk, and reaches the abdomen and mesenteric glands through the intestines. Several clinical varieties exist, and can be enumerated as follows.

1. *Tuberculous Ascites.*—The peritoneum and mesenteric glands are both infected with tubercle, which produces a gradually increased accumulation of fluid in the abdominal cavity. This may lie free in the abdomen or be loculated by the presence of adhesions.

2. *Tabes Mesenterica.*—The infection is confined to the abdominal glands, which become caseous or calcified. They may give rise to symptoms, or remain quiescent and be found unexpectedly at operation or post mortem.

3. *Adhesive Peritonitis.*—In this condition there is little or no free fluid present. Matting of the mesentery and omentum occurs, and adhesions are formed between the coils of intestines.

4. *Tuberculous Ulceration of the Bowels.*—This is generally secondary to pulmonary disease, resulting from the swallowing of infected sputum. In children it can occur as a primary infection, and is then usually associated with severe involvement of the mesenteric glands. In either case diarrhoea is the most striking symptom.

5. *Intestinal Obstruction.*—This may result from ulceration of bowel, or from kinking and narrowing of its lumen through peritoneal adhesions.

6. *Acute Peritonitis.*—This is simulated occasionally when an intestinal ulcer perforates into the surrounding adhesions, or when a tuberculous gland breaks down completely or becomes infected with other organisms.

Clinical Manifestations.

The symptoms depend largely on the part first and most severely affected, but generally they are gradual and insidious. The child's strength is noticed to be failing; he is pale and thin, feverish at night, and the abdomen is progressively enlarging. The appetite is capricious, the stools are often unhealthy, and there may be alternating constipation and diarrhoea. Attacks of colic are not uncommon, and when associated with vomiting may be mistaken for subacute appendicitis. In those cases which simulate acute peritonitis the onset of symptoms is very abrupt, with high temperature, vomiting, acute abdominal pain, and generalized tenderness and rigidity. When the acute inflammation is principally confined to the ileo-caecal glands, this tenderness and rigidity is localized to the right iliac fossa, and the condition closely resembles acute appendicitis. The adhesive type may so constrict the intestines and interfere with their normal movements that partial obstruction results; the intestinal coils stand out in relief under the abdominal wall, and peristalsis may be seen. In certain mild cases there are repeated feverish attacks at intervals of a few months, and little else is noticed at the time except slight abdominal distension. Enlarged glands or tuberculous masses, sometimes mistaken for the liver, can usually be felt in the abdomen at some period of the disease, but these may be masked by the presence of ascites. When suppuration occurs the abscess always tends to point at the umbilicus.

The outlook is certainly favourable in the absence of any severe tuberculosis elsewhere, and patients who have received prompt and energetic treatment recover completely. No case should be despaired of, since the disease rarely proves fatal, and then only in very feeble children. The infection is more dangerous in infants, in whom it is apt to spread beyond the abdomen.

Treatment.

The patients must live in the open air day and night, and remain flat in bed so long as ascites continues, the temperature is raised, or there are any other symptoms present. The general resistance is increased by giving as much nourishment as possible without upsetting the digestion. Milk, cream, eggs, butter, plasmon, raw meat juice, and raw meat sandwiches should all be included in the diet; but if they are not tolerated, and cause flatulence and curdled stools, fats must be restricted and milk may require peptonizing. Starchy foods are contraindicated, and if the appetite is poor or the digestion weak, alcohol in the form of brandy or brandy egg-flip should be given. Cod-liver oil is valuable, but cannot be added to the diet unless the stools are normal and there is no diarrhoea.

A belladonna and glycerin liniment (1 to 4) applied to the abdomen on lint is helpful in easing pain. Various applications are also said to be useful in the treatment of the peritoneal disease, but, with the possible exception of 5 per cent. ointment (10 per cent.) and mercury ointment (½ strength), they are of little value.

Irradiation of the abdomen by natural sunlight or ultra-violet rays is undoubtedly beneficial. If the ascites continues to increase, its removal may become necessary by means of a small trocar and cannula or Southey's tubes; but the best method of drainage is through a fairly long incision under general anaesthesia. Surgical removal of tuberculous abdominal glands is an unsuccessful procedure when there are any considerable number, and in adhesive tuberculous peritonitis surgery is positively dangerous and liable to liberate the contents of the bowel into the abdominal cavity. It is equally unwise to interfere with a tuberculous abscess until it is actually on the point of bursting through the umbilicus.

Tuberculosis of the Ear.

Chronic discharge from the ear in children is more commonly due to tuberculous infections than is usually supposed. Any aural discharge in a suspected case of tuberculosis should be examined, since the chance discovery of tubercle bacilli may just give the required confirmatory evidence. There are few subjective symptoms, and the ear continues to discharge profusely, despite ordinary methods of treatment. The lymphatic glands in the vicinity of the mastoid soon become infected and finally break down. In addition, there may be facial palsy as a result of involvement of the facial nerve as it passes through the middle ear. In the treatment efforts are made to eradicate the disease completely by surgical means, but this is often unsuccessful and the outlook is generally unfavourable.

Tuberculous Meningitis.

No disease in the whole of paediatrics can appear in so many unexpected ways as tuberculous meningitis and lead to such confusion. The illness has no classical picture, and such physical signs as do appear often arise so late that they give no help towards an early diagnosis. Little reliance should be placed on Koenig's sign, as it is very inconstant and its absence in no way precludes the presence of tuberculous meningitis. Severe headache, persistent vomiting, prolonged pyrexia, gradual change of temperament, drowsiness, or a sudden fit followed by unconsciousness are all possible modes of onset. Should any of these occur after infancy and have no other explanation, tuberculous meningitis should always be borne in mind. Two physical signs that I have found most useful in a doubtful case are enlargement of the spleen and a unilateral extensor response. The ultimate diagnosis will, however, depend upon examination of the cerebro-spinal fluid, and, once established, the prognosis is invariably fatal.

Conclusion.

Let me emphasize once again the importance of prophylaxis. The prevention of contact with human sources of infection, the proper sterilization of milk, the maintenance of a high standard of general bodily health, and the provision of adequate country or seaside convalescence after any severe infection are the best safeguards we can give a child against tuberculosis.

CERTAIN ASPECTS OF THE DIAGNOSIS AND TREATMENT OF DIABETES.*

BY

S. C. DYKE, D.M., M.R.C.P.,

CONSULTING PATHOLOGIST, THE ROYAL HOSPITAL, WOLVERHAMPTON.

In the past the identification of a reducing substance in the urine sufficed for the diagnosis of diabetes. Varying degrees of severity were recognized, but anyone presenting a urine which reduced Fehling's solution was regarded as suffering from diabetes of greater or lesser severity. That parturient women and nursing mothers frequently showed sugar in the urine was early recognized, but it was some time before it was realized that this sugar was lactose and that its presence lacked any particular significance. Later it was discovered that the urine of certain persons otherwise in normal health contained pentose, which reduces Fehling's solution in the same manner as glucose. For the diagnosis of diabetes it was then deemed only necessary to demonstrate that the reducing substance in the urine was neither lactose nor pentose, the former being readily excluded by the yeast fermentation test with which it gives a negative result, the latter by Bial's reaction.

*A paper read before the South Staffordshire Division of the British Medical Association at Walsall on March 21st, 1929.

the diagnosis of diabetes thus came to depend upon the demonstration of glucose in the urine. All patients consistently showing glucose in the urine on an ordinary diet were regarded as diabetics.

TYPES OF BLOOD SUGAR CURVE.

It was long ago shown that the glycosuria of diabetes is dependent upon the presence of an unusually high percentage of sugar in the blood; in the absence of any easy means of examining the blood sugar level, however, it was not possible to apply this knowledge to the differentiation of the various types of glycosuria. With the invention of quick and simple means for measuring the blood sugar, such as those devised by MacLean, Folin, Benedict, and many others, it became feasible to estimate the blood sugar clinically, and it then became apparent that the percentage of sugar in the blood is subject to fluctuations according to the stage of digestion. In normal persons the blood sugar between three and four hours after a meal falls to a level of somewhere between 80 and 120 mg. per cent., which may be known as the fasting level. On the ingestion of food, particularly of starchy food, it rises rapidly to from 180 to 200 mg. per cent., and then falls rapidly again, reaching the original fasting level in between one and a half and two and a half hours.

In diabetics the behaviour of the blood sugar is quite different. In the first place, even after a prolonged fast, the level is usually much above the normal fasting level. On the ingestion of food it rises rapidly to a level far above that ever attained in normal persons, and stays up. It is this persistence of a high blood sugar after the ingestion of food which characterizes the diabetic—in other words, it is the shape and not the height attained by the blood sugar curve which is diagnostic of diabetes. In partially treated cases the fasting level of the blood sugar may be normal, and even after the ingestion of glucose it may rise only just above the level to be expected in a normal person; but having risen, there it stays, thus making clear the diagnosis of diabetes.

The blood sugar in normal persons can hardly be made to rise above from 180 to 200 mg. per cent. If it be induced to do so sugar is excreted in the urine. The blood sugar level at which sugar is excreted in the urine is known as the "renal threshold" for glucose. In some persons otherwise quite normal this renal threshold may be lower than usual, their condition, which is without clinical significance, being usually known as "leaky kidney" or "renal glycosuria." Yet another type of glycosuria which must be distinguished from true diabetes is found in some persons in whom, after the ingestion of sugar, the blood sugar rises steeply to an abnormal level, but thereafter falls to the fasting level in the normal time. This is a comparatively rare condition, and its significance is obscure; in view of the fact, however, that persons in whom it is found often pass acetone in the urine it would seem to indicate a definite disturbance in carbohydrate metabolism and to demand a careful observation of the patient.

It is obvious, then, that the mere presence of sugar in the urine cannot be looked upon as establishing a diagnosis of diabetes. An examination of the fasting blood sugar, taken from three to four hours after the last meal, is also necessary. If this shows a high blood sugar the diagnosis is more or less complete; if the blood sugar is at, or not much above, the normal level, a glucose tolerance estimation and a blood sugar curve can hardly fail to establish the diagnosis one way or the other. Further evidence must be sought in the presence or absence of the ketone bodies, acetone and diacetic acid. Their presence along with sugar is strongly indicative of the existence of true diabetes; in their absence diabetes, even if present, is probably of a mild type. The presence of acetone in large amount is a danger signal; the presence of diacetic acid in any amount is a call for instant and vigorous treatment.

PROBLEMS IN THE TREATMENT OF DIABETES.

Everyone who has seen more than one case must recognize that diabetes varies enormously in severity. It is a commonplace that it is severe in the young and that the later in life it develops the more benign it becomes. The presence or absence of the ketone bodies serves as some indication of severity or benignity. Much information can also be derived from the appearance of the patient. The young or middle-aged patient, showing a dirty tongue, complaining of polyuria and thirst, and showing signs of recent loss of weight, is obviously in a more dangerous state than the elderly, apple-faced, and obese individual, boasting of a hearty appetite, and in whose urine sugar has been discovered by chance only. In the former class the indications for immediate and vigorous treatment are obvious; in the latter it must be decided how far one is justified in meddling with a regime upon which the patient feels perfectly well. The existence of pruritus, neuritis, or ocular or cardiac trouble of any sort is a distinct indication for treatment; if, in the absence of these conditions, patients choose to go their own way, they should always be warned of the danger of gangrene.

Treatment of diabetes has practically only one object in view—namely, to reduce the work of the islet cells of the pancreas to a level with which they can cope. The islet cells seem to be peculiar among the cells of the body in that they are only just up to their work. The amount of overloading which they will sustain without collapse is limited. In these latter years it has become the custom to sing the praises of a carbohydrate diet and to attribute all sorts of ills to the proteins, especially to those of "red" meat. In America, where food fads flourish to an extent even greater than in this country, and where the inhabitants are in the habit of stoking up, especially at breakfast, on farinaceous foods of all sorts, diabetes is rapidly on the increase; its heavy incidence among the *rice and sweetmeat-eating Bengalis is well known*. My own observations would lead me to believe that it is also on the increase in this country, a fact which may be correlated with the demand, attested by the butchers throughout the land, for smaller joints.

How readily a normal pancreas will collapse it is difficult to say; many diabetics show a history of diabetes in the family; in others the onset may follow on an acute illness; in many cases no predisposing cause is to be found. Such sporadic cases are usually severe, and may be due, as suggested by Cammidge, to the inheritance of the diabetic tendency as a recessive, in which case a family history would be difficult to obtain.

In children, no matter how it occurs, the condition is always dangerous and difficult to treat; in young adults surprisingly good results may be obtained once the load is removed from the pancreas by means of insulin and diet. In all cases except the mildest, such as occur in the elderly, it is advisable to have recourse to insulin early in treatment, but in many cases in youngish persons the islet cells of the pancreas may regain their powers to such an extent that the dose of insulin may later be progressively reduced and sometimes dispensed with altogether.

Only recently diet was our sheet anchor in the treatment of diabetes; it still remains a vastly important factor, but we are coming to rely more and more upon insulin, even in mild cases. Until lately it was my custom to fast patients until they were sugar-free, and then to try to build up a diet on which they would remain free without the use of insulin. If possible I liked to send them out on diet alone. My present procedure is still much the same, but I no longer hesitate to use insulin early if there is the slightest difficulty about building up a suitable diet without it. In the case of patients who do not baulk at the thought of insulin, which most do until they have had experience of it, I encourage its use even if their case can be controlled without it, as by its use a greater laxity of diet becomes permissible, with a corresponding increase in the comfort of the patient.

The Administration of Insulin.

Patients should always be taught to administer their own insulin, or, at any rate, to have it administered by someone, be it nurse or relative, constantly about their persons. To this rule there is no exception. Insulin must be given within twenty minutes of the commencement of a meal, and always before the same meals. It is impossible for a practitioner to attend his diabetic patients once or twice daily always in the same relationship to meals, and the custom of administering a dose at any odd time during the

day cannot be too strongly condemned. Once the ice has been broken patients usually administer their own insulin without trouble. For both men and women the abdominal wall makes an admirable site for the before breakfast dose; men usually prefer to give doses during the day into the leg below the knee, while women usually select the thigh. In all these sites it is possible to steady the skin with one hand and to give the injection with the other. Patients should be instructed to keep their syringes in spirit and to wash them out with tap water before and after use. This latter point is of importance, as traces of spirit in the syringe will irritate the skin and may even cause ulceration. An intelligent patient can arrange matters so that the administration of insulin even three times daily makes but little difference to the enjoyment of life; there are many such who lead active lives at business or participate vigorously in sports, both in spite and because of three doses of insulin daily.

In all but the simplest cases the determination of the suitable insulin dosage is a matter of some difficulty, and cannot be made without careful watching of the patient. On the whole it may be said that it is better to give too much than too little: hypoglycaemia is something of a bugbear, and the symptoms should be explained to the patient, who should be warned to carry a few lumps of sugar at all times, and to suck a lump if troubled by feelings of giddiness. I have seen two patients rendered unconscious by hypoglycaemia; one of them received 80 units of insulin on the assumption that the condition was coma, but both made perfect recoveries and suffered no ill effects. Most cases of hypoglycaemia will respond readily to a hypodermic injection of 1 c.cm. of adrenaline followed by sugar by the mouth as consciousness returns. It is seldom, if ever, necessary to give sugar intravenously in such cases. Mild hypoglycaemia symptoms are common in patients on a sufficient insulin dosage, but usually pass off without treatment. In its mildest form hypoglycaemia is shown by flushing of the face, giddiness, and a feeling of lightheadedness. As it proceeds there may be inco-ordination and incoherence of speech, and later unconsciousness.

From time to time cases may be met with which prove resistant to insulin. This resistance may be of a high degree, so that even with large doses it may be difficult or even impossible to keep down the blood sugar level. Such a condition developing in an elderly diabetic without apparent cause is usually an indication of the development of some constitutional disorder such as cancer or tuberculosis; it may occur acutely in diabetics suffering from severe infections such as erysipelas, or it may occur from no apparent cause in diabetics who have apparently been doing well for some time. In one such case at necropsy I found such islets as remained in the pancreas engorged to the point of destruction with blood—an apparent apoplexy of the islets. In all such cases the outlook is grave in the extreme. Other milder cases may show a fluctuating response to insulin, so that with the patient on a fixed diet the same dose of insulin may at one time fail to control the blood sugar, and at another may produce hypoglycaemia. Such a condition usually indicates the presence of a focus of active sepsis, and is an indication for a careful examination of such possible sites as the tonsils, teeth, accessory sinuses, appendix, and gall-bladder. Eradication of the focus of sepsis has the happiest results.

Diabetic Coma.

The menace of coma perpetually hangs over the head of the diabetic patient and of his doctor. Apart, however, from the cases referred to above, which for some reason or other become insulin-resistant, it may be said that the onset of coma is indicative of gross carelessness either on the part of the patient or the doctor. So far as subjective symptoms are concerned it may fall on the patient with as little warning as a thunderbolt, but acetone will have been present in the breath and ketone bodies in the urine for weeks beforehand. Cases have been reported in which there was no acetonuria, but it is difficult to believe that the coma was diabetic. Coma is unusual in patients who are taking anything like a sufficient insulin dosage, but it may occur when the dose in insufficient, and in these circumstances there is always some doubt as to whether the unconsciousness is due to diabetes or to insulin hypoglycaemia. The presence of sugar and ketone bodies in the urine is strong evidence in favour of coma. A high blood sugar in conjunction with ketone bodies in the urine makes the diagnosis to all intents and purposes certain. Where means of investigating the blood sugar and urine are not available it is possible to make a fairly certain diagnosis on the history and the clinical appearance. Patients in advanced hypoglycaemia show a moist skin, flushed face, and a bounding pulse; their respiration is deep, but not stertorous. Patients in coma show a dry skin, a pale face, and a weak pulse; in the later stages their respiration is usually stertorous, and the Babinski reflex may be plantar in type. In addition, for those who can smell it, there is the odour of acetone—the odour of sanctity of the hagiologists. The management of coma demands constant care and attention. The enemies to be combated are hyperglycaemia, acetonaemia, and heart failure. Insulin is the first requisite, and should be given at once in a dose of from 80 to 100 units. It is my custom to combine it with sugar by the mouth with a view to combating the acetonaemia. Since there is already excess of sugar in the blood this may seem irrational, but it works well in practice. It was formerly our custom to treat coma with large doses of sodium bicarbonate given by the mouth. In a small series of cases treated with and without the alkali at the Royal Hospital we found, however, that those not given the bicarbonate did best; and in view of this and of certain experimental evidence that excess of alkali interferes with the metabolism of carbohydrate, we have discontinued its use in large doses. In cases in which, as often occurs, the blood is thick and viscous, intravenous injection of saline is indicated. There is some evidence that in coma there is a diminution of the chlorides in the blood, and having this in mind, and with a view to bringing about a dilution of the blood by osmosis from the tissues, we have lately been trying the effect of the injection of a solution containing 2 per cent. sodium chloride and 5 per cent. sodium bicarbonate. It is too early yet to report on this measure.

After the initial dose of insulin further doses must be controlled by the blood sugar; usually a further 40 units or so is required within about two hours, and thereafter not more than 10 units hourly. I have found no benefit in the administration of the immense doses advocated by some authors. Next to giving insulin the most important step is to get the bowels open, and to this end enemata should be continued until a good result has been obtained. The state of the heart will demand attention, and in most cases the hypodermic injection of camphor in oil will be indicated early in the course of the condition. The patient must be kept warm with hot-water bottles, and large amounts of fluid, preferably water, must be administered—if possible by the mouth, but otherwise by the rectum or subcutaneously.

By these means it will be possible in most cases of coma, except in those dependent upon the existence of some acute infection, to reduce the blood sugar to normal and to free the urine from acetone. Even when this result has been brought about, however, the issue may be fatal; cases occur in which unconsciousness persists and death results in spite of a normal blood sugar and a urine free of acetone. The diabetic once in coma cannot be regarded as out of the wood until he has been conscious for several days and showing a normal blood sugar and urine. I have known patients admitted to hospital in coma to relapse twice, the second time fatally.

Diabetes Complicated by Sepsis.

The existence of any septic condition, whether it be an acute infection, a carbuncle, or a limb affected by "wet" gangrene, complicates the management of a diabetic case and facilitates the onset of coma. In such cases it is of primary importance to get the urine free of acetone and to keep it so. To this end there must be no restriction of the carbohydrate in the diet; a liberal amount must be taken and balanced by sufficient doses of insulin. It is usually desirable for the patient to take between 80 and 100 grams of carbohydrate daily, the form being immaterial. In very severe infections glucose water or fruit juice may be the most convenient form; Benger's food is usually well

rated, and in milder conditions the bulk of the carbohydrate may be taken as bread. The following skeleton t, which may be modified to suit the particular case, is use at the Royal Hospital.

leat, fish, poultry, eggs, clear soup, bovril, broth, cabbage, liflower, lettuce, endive, tomato, grape fruit, asparagus, mushms, sea-kale, cucumber, chicory, spinach, celery (*as desired*). 'ea, coffee, and unsweetened lemon juice in water (*as desired*).

Compulsory Ration.

unger's food made with milk ..... half pints during the day.
. units of insulin are to be taken before each half-pint of ager's food.
Bread .. ounces during the day, with meals. Butter as ired.
If specially ordered) *Jam or preserve*—half an ounce with ad, at a meal.
A further .. units of insulin is to be taken before ..... the daily meals, one of which must be the one at which the n is taken (if ordered).
Total daily insulin dosage ..... units.
Carbohydrate approximately ..... grams.

CARE OF DIABETICS BEFORE AND AFTER OPERATION.

In operations upon diabetic patients it is a matter of e utmost importance to avoid ketosis. For a clean eration, such as an interval appendix or radical cure a hernia in a well-controlled diabetic, few special preutions are necessary. Where, however, there is sepsis, in the case of amputation of an extremity for wet angrene or the excision of a carbuncle, it is well, if ssible, to delay the operation until the diabetes has to me extent been controlled. The following procedure, bject of course to modification to suit the individual se, is the routine at the Royal Hospital.

1 Three days prior to operation increase the carbohydrate ntent of the diet to at least 100 grams.
2. Operate early in day.
3. Three hours before operation give carbohydrate content of sual breakfast *plus* 10 grams of glucose. Give usual morning nsulin at same time.
4. Simple enema one and a half hours before operation.
5. *Immediately before operation give 10 to 20 units of insulin.*
6. On returning to ward give 30 to 40 grams of glucose as 0 per cent. solution in saline, rectally, with 20 to 30 units of nsulin.
7. Two hours after operation take blood specimen and give lucose or insulin according to result.

The diet in early days after operation should be liquid nd soft, and should largely consist of carbohydrate until he temperature is normal and manifestations of toxaemia ave disappeared. The total calories should not exceed naintenance diet during the period of active healing.

In conclusion, I would insist that the successful treatment of diabetes demands the whole-hearted co-operation of the patient. He must have an intelligent appreciation of the condition from which he is suffering, and time spent in explaining this to him is time well spent by his medical attendant.

COLLES'S FRACTURE:

AN EFFICIENT AND ECONOMICAL METHOD OF SPLINTING.

BY

W. MITCHELL SMITH, M.D., C.M.,

HONORARY ORTHOPAEDIC SURGEON, CRIPPLES' HOSPITAL, STOKE-ON-TRENT.

THE cost of after-care (massage, physiotherapy, and electrotherapy) in the treatment of fractures has been mounting up in recent years to an alarming extent. The time has come for the surgeon who prescribes this treatment—often as a matter of routine—to consider whether this expense is justified, or whether equally good, or even better, results might not be obtained by well-considered splinting.

Efficient splinting should ensure complete immobilization of the fragments after reduction, and, in the case of the Colles's fracture, fixation of the hand in such a position that the patient is able to use it as soon as the damage to the soft tissues begins to subside. Jones's and Carr's splints are the two most commonly used. The former provides the more perfect fixation of the fragments; the latter the better position from which to start re-education. I find that the best features of both splints can be combined in a carefully applied plaster case.

The treatment of a Colles's fracture may be divided into three stages: (*a*) reduction of the fracture; (*b*) splinting; (*c*) after-care.

A. *Reduction of the Fracture.*

Reduction of the fracture under an anaesthetic can generally be easily obtained by steady traction on the hand and manipulation of the fragments into position by the thumb and forefinger. If more force is required the well-known manipulation of Sir Robert Jones provides all that is necessary; but as little force should be used as possible. Complete reduction is indicated by the restoration of the radial curve, as described by Sir Robert Jones, and of the correct relationship of the styloid processes.

B. *Splinting.*

A roll of stockinette is run up the arm, extending from the knuckles to the elbow. Over this a light plaster case is applied. With the thumb and forefinger of one hand the surgeon holds the fragments of the radius in the corrected position, and with the other hand holds the wrist in about 15 degrees of dorsiflexion and slight ulnar deviation while the plaster sets. It is essential that the plaster should be closely moulded to the dorsum of the wrist and that the angle of dorsiflexion should be exactly opposite the joint. To prevent rubbing the skin, the plaster should extend, glove fashion, half-way up the metacarpals, and should allow full palmar flexion of the metacarpo-phalangeal joints. (Figs. 1 and 2.)

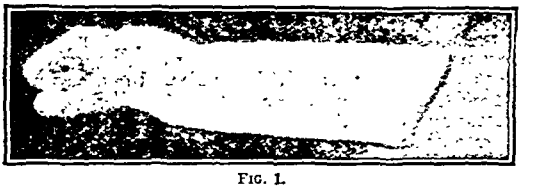

FIG. 1.

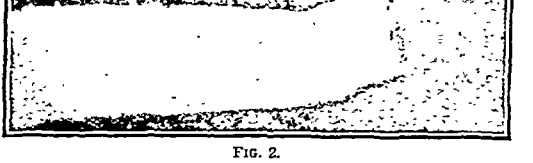

FIG. 2.

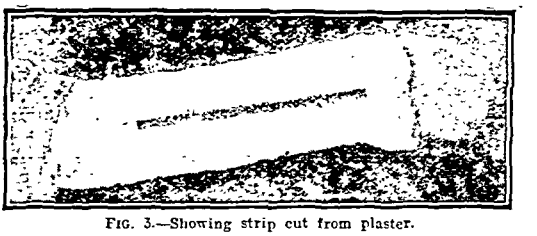

FIG. 3.—Showing strip cut from plaster.

The occurrence of pain and swelling of the fingers may be avoided by cutting out from the back of the plaster, before it sets, and from the underlying stockinette, a strip about half an inch wide, leaving a bridge at the top and the bottom (Fig. 3). A radiogram to confirm the correction should be taken through the plaster.

C. *After-care.*

As soon as he recovers from the anaesthetic the patient is encouraged to use his fingers and gradually to develop the use of his hand. In a week or ten days he is able to do anything within the limits imposed by a cock-up splint. The plaster case is removed at the end of a month, by which time bony union has generally taken place, and as

the patient has already been using his hand freely for two or three weeks no further treatment is required.

I have been treating Colles's fractures by this method for the past three or four years with uniformly good results and with considerable saving in the cost of treatment.

HYPERSPLENISM AND HYPOSPLENISM AND SPLENECTOMY.

BY

F. PARKES WEBER, M.D., F.R.C.P.

APART from the results of traumatism and the exceedingly rare primary malignant neoplasms and some of the primary (or "predominant") tuberculous and other chronic infectious (parasitic) conditions of the spleen, the indications and counterindications for splenectomy will doubtless be more definitely formulated when more is known about the various functions of the organ in question. In regard to *the functional activity of the spleen it will probably* become more and more convenient to speak of "hypersplenism" and "hyposplenism"—by analogy with the terms "hyperthyroidism" and "hypothyroidism," "hyperpituitarism" and "hypopituitarism." It will probably also be found that there are various forms of hypersplenism and hyposplenism corresponding to involvement of the various functions of the spleen (and reticulo-endothelial system), apart from the now well-recognized function of the spleen as a blood reservoir (Barcroft, etc.).

In cases of harmful (not compensatory) hypersplenism splenectomy or some effective depressor of splenic function (radium, *x* rays, and other as yet undiscovered means) will be indicated. At present splenectomy is not rarely (sometimes with excellent result) performed for conditions, such as congenital haemolytic jaundice, thrombocytopenic purpura haemorrhagica, and the Gaucher type of splenomegaly, where there is more or less clinical evidence of hypersplenism. For cases of hyposplenism some effective activator of the spleen and reticulo-endothelial system will have to be searched out.

In regard to splenic infections it should be remembered that, though one of the functions of the spleen, as of the tonsils, is to resist and "hold up" infections, the spleen sometimes, like the tonsils, may become so overwhelmed as itself to constitute a harmful focus of infection—a state of affairs for which splenectomy may constitute a rational part of the treatment. In some such cases the bulk and altered consistence of the enlarged spleen may themselves become a source of danger for the individual (possibility of rupture from relatively slight traumata).

Under infectious and parasitic splenomegalies, besides the relatively transitory enlargements due to the ordinary acute febrile infections, one would place the more chronic ones due to malaria, syphilis, tuberculosis, hydatid cysts, kala-azar, schistosomiasis (one form of "Egyptian splenomegaly"), the problematic splenic "mycoses," and perhaps certain other cases that have been clinically labelled as "Banti's disease."

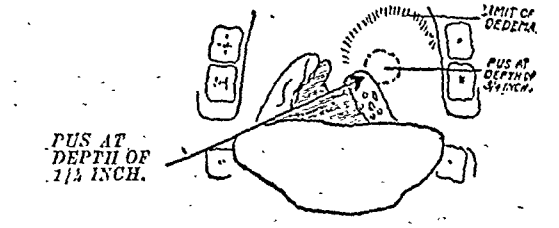
Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE ANATOMICAL METHOD OF OPENING QUINSY.

NOT everyone has been satisfied with the old method of opening quinsy by cutting into the soft palate. The oedema present often makes it difficult to find the pus, and more than one cut may be necessary. On the other hand, immediate enucleation is so drastic a form of treatment as to appear unnecessary as well as risky. Both of these extremes can be avoided by opening the abscess in the right way.

A quinsy is a collection of pus in the supratonsillar fossa. It forms because of inflammatory adhesions at the normal orifice of the fossa. As pus accumulates the palate bu... and is further swollen by oedema. In order to evacuate t... pus it is only necessary to break down the adhesions b... introducing a pair of sinus forceps with closed blades in... the supratonsillar fossa in the direction shown by the ar... in the diagram. The point of insertion is immediat...



under the arch formed by the anterior and posterior faucial pillars on the same side. A slight push is needed. As soon as they have penetrated the abscess the blades are widely opened, the adhesions are broken down, and pus pours out.

There are many advantages in this method:

1. It is simple, certain, easy, and only one instrument is required.
2. Trismus is no obstacle.
3. There is no pain beyond pressure from the forceps points.
4. There is hardly any bleeding because nothing is cut.
5. The abscess is freely drained by its natural outlet.
6. The tonsils can be enucleated without risk at a later date.
7. There is no unnecessary mutilation of mobile parts.
8. No anaesthetic is necessary, either local or general.

London, W. H. MORTIMER WHARRY, F.R.C.S.

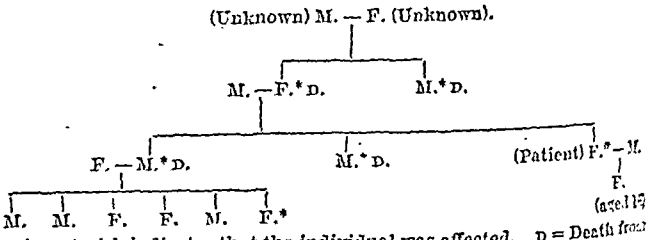
HEREDITARY ANGIO-NEUROTIC OEDEMA.

THAT heredity plays an important part in the causation of Quincke's disease is well established, and numerous authors have reported genealogies. The hereditary form would seem to be of a much more severe type than the comparatively common acquired cases, and this is illustrated by the cases of Griffith,[1] where both father and daughter died of acute oedema of the larynx. J. R. and T. R. Crowder[2] report five generations of a family, and 63 known descendants 27 inherited it; of these, 14 died as a direct result. Although a number of cases are on record, the hereditary form would appear to be of sufficient rarity in the individual experience to justify a case report.

A woman, aged 55, was referred to me on account of angio-neurotic oedema of lifelong duration; the disease was of the cutaneous type, and there was a complete absence of any of the puzzling attacks of abdominal colic due to intestinal oedema. The attacks occurred every two or three weeks, and the reason that advice was sought was the alarming increase in severity and frequency of the laryngeal involvement; the areas of oedema were peculiar in the absence of itching. Physical examination revealed little apart from a slight degree of dermatographia, much less than is usually seen in the common variety of case.

The patient was considerably apprehensive as to the outcome of the disease, as her mother and her only two brothers died of it in an effort to avert the family tragedy the patient was desensitized by a course of peptone in small doses, and she was instructed to ingest half a grain of ephedrine sulphate at the first warning of an attack. Up to the time of writing the results have been most happy.

The following is the genealogical tree.



An asterisk indicates that the individual was affected. D = Death from oedema of the larynx. M. = Male. F. = Female.

ERNEST BULMER, M.D.,
Assistant Physician, General Hospital, Birmingham.

Reports of Societies.

DISSEMINATED ENCEPHALO-MYELITIS.

At a meeting of the Section of Neurology of the Royal Society of Medicine, on April 11th, the subject of disseminated encephalo-myelitis was discussed, with Mr. DONALD ARMOUR in the chair.

Dr. W. J. ADIE said that the incidence of acute disseminated encephalo-myelitis had recently assumed almost epidemic proportions. He gave an account of the clinical features of the diffuse and disseminated forms, and suggested a number of questions for discussion, in particular as to the relation of acute disseminated encephalo-myelitis to disseminated sclerosis. Was disseminated sclerosis also caused by a filter-passing virus? Was it caused by the same virus that produced all the other diseases of this group in which the white matter was mainly affected? His own opinion was that disseminated sclerosis was probably due to a virus belonging to the same group, but that there was not evidence to prove that it was the same virus. He mentioned several instances in which retrobulbar neuritis had been followed by other symptoms of disseminated sclerosis after a period of several years.

Dr. J. G. GREENFIELD dealt with the histological similarities of encephalitis, diffuse myelitis, and acute disseminated encephalo-myelitis, such as occurred after vaccination, measles, and so forth. These diseases all had certain points of similarity to disseminated sclerosis, but histologically they were more related to one another than to that condition. He described two fatal cases in men, seen within the last month, of myelitis coming on after an attack of influenza, both of them being associated with a lesion, so far as he could tell, histologically identical with post-vaccinal encephalo-myelitis. He thought that these cases, with other accumulated data, indicated that in these diseases there was evidence of some toxin present in the nervous system, which was stimulated to activity when the onset of some febrile disease lowered the patient's resistance.

Dr. GEORGE RIDDOCH pleaded for an open mind about the whole situation. In the recent epidemic of influenza he had been greatly puzzled by the multifarious character of the neurological sequelae. He brought forward fourteen cases with a typical influenzal story which had gross neurological manifestations; how to classify them he did not know. None of the patients died. The cerebro-spinal fluid was examined in several and no abnormalities were found. He could not determine the meaning of this heterogeneous group of neurological disorders. The only position for the clinician to take up was to obtain all the help he could from the histologist and pathologist, and to keep an open mind on the problem.

Dr. GORDON HOLMES referred to the occurrence of this disease in previous epidemics, though of limited extent. There was a very definite outbreak of diffuse myelitis and diffuse encephalo-myelitis in the winter of 1905. During the war, in the winter of 1917–18, he saw among the troops a number of cases of a similar disorder. These cases certainly ran a very characteristic course. A certain proportion of them went in a step-like manner, new attacks of the disease occurring after an interval of weeks or months. He had frequently seen remarkable instances of recovery, but many cases, on the other hand, did not recover.

Dr. C. P. SYMONDS, referring to Dr. Adie's remark about the association of retrobulbar neuritis with disseminated sclerosis, said he had seen an instance in which twenty-four years had elapsed between the attack of retrobulbar neuritis, first in one eye and then in the other, and subsequent symptoms typical of disseminated sclerosis. He was sceptical as to the distinction between neuromyelitis optica and disseminated sclerosis. He thought that there were grounds, on both the clinical and the pathological side, for doubting whether the distinction was a true one.

Dr. W. R. BRAIN, after describing some cases, said that the difficulties of classification could only be solved by close co-operation between pathologists and clinicians. One possibility was that the differences in the response shown by the individual to neuromyelitis optica and to disseminated sclerosis might be due to differences of immunity. It was possible that in myelitis the patient received a large dose of virus, and either died or developed complete immunity, whereas in disseminated sclerosis the immunity might be incomplete, with the result that the disease pursued its characteristic course of remissions and relapses.

Dr. PARKES WEBER made a remark about a nervous symptom which had been observed in connexion with influenza and which, he thought, had some bearing on the subject. A middle-aged man was recovering from influenzal broncho-pneumonia when he suddenly developed incontinence of faeces. The sphincter was completely paralysed. This was the first case the speaker had seen of paralysis of the anus following, or being connected with, influenza. This man, under treatment, gradually recovered. A colleague who saw this case with the speaker went to Hamburg, and from there he had written within the last few days stating that he had seen another man suffering from influenza with complete paralysis of the rectum; this case had terminated fatally.

PATHOLOGY OF CERVICITIS.

A MEETING of the North of England Gynaecological and Obstetrical Society was held in Liverpool on March 15th, with the president, Dr. G. W. FITZGERALD (Manchester), in the chair. Dr. K. V. BAILEY read a paper on the pathology of cervicitis.

Dr. K. V. Bailey said he had examined 650 specimens of the cervix uteri with a twofold object: (1) to ascertain the precise pathology of the so-called cervical erosion, and (2) with a thorough knowledge of this pathology as a basis to inquire into the problem of the inception of cervical cancer. He considered that there were two types of pathology of cervicitis. (1) The relatively unimportant and rare condition of congenital erosion was seen in the nulliparous and presumably non-infected cervix. Moench and Reel had described this condition, and considered it due to anomalous growth of the mucous membrane lining the cervical canal. In the speaker's series this type showed definite inflammatory reaction, and, therefore, there was no reason to distinguish it from the inflammatory type. (2) The large group of inflammatory erosions. Dr. Bailey believed that the life-history of this condition fell into four distinct stages. Stage 1: The primary effects of irritation. This stage was characterized microscopically by the stripping off bodily of the squamous epithelium at the level of its lowermost cells by large and small blood cells, and the inflammatory exudate as a whole. Stage 2: Epithelial reaction to inflammatory irritation. This was the stage of proliferation and repair; microscopically the evidences of inflammatory reaction were definitely lessened. The surface exudate was less, and intimately associated with the new surface epithelial covering, which was identical with, and derived from, the columnar epithelium lining the cervical canal. Stage 3: Replacement of columnar by squamous epithelium on the surface of the affected area. In this stage the squamous epithelium grew over the affected area by new cells arising from the basal layer of the nearest unaffected squamous epithelium; it extended upwards towards the adjacent columnar epithelial surface, and lifted the single layer upwards in a lever fashion, thereby gradually replacing it. In this stage the tissues immediately beneath the columnar epithelial layers were greatly rarefied. Stage 4: Ultimate healing. This stage was characterized by the presence of dilated gland spaces situated beneath the new covering, the result of mechanical blocking of their ducts by the squamous cells. Pseudo-malignant appearances resulted from irregular down-growths of squamous cells, especially in connexion with the mouths of dil gland spaces. Dr. Bailey had found forty-two examples his series of a true ulcerative erosion of the cervix which was pathologically akin to the condition already described. The affected area was depressed with overhanging epithelial edges in immediate contact, and a smooth granular depressed base coated with chronic exudative material. It was a condition relatively common in association with the damaged and hypertrophied cervix usually removed during the operation for uterine prolapse.

The speaker suggested that from the pathological standpoint the term "erosion" was erroneous. He suggested that the group of cases known as erosion ("papillary," "follicular," etc.) should be called "peri-orbicular cervicitis"; that true ulceration of the cervix should be termed "ulcerative cervicitis"; and that infection limited to the cervical glands should be called "glandular cervicitis."

Rupture of the Caesarean Scar.

Professor Blair Bell (Liverpool) showed a specimen of a uterus with the scar of a Caesarean wound. This specimen had been obtained at the post-mortem examination of a patient who died a few hours after an emergency Caesarean section. It demonstrated clearly the result of the procedure advocated by the exhibitor, and described by him in the *Journal of Obstetrics and Gynaecology of the British Empire*, 1925, xxxii, p. 727. The strong, heaped muscular scar, the absence of catgut on the peritoneal and mucosal surfaces, and the complete apposition of the parts were revealed. The speaker said that the question of rupture of the Caesarean scar had often been discussed, and cases had been admitted to the Royal Infirmary in the last few years of both rupture and impending rupture. He knew of no case of his own in which such conditions had supervened. It was, of course, obvious that infection in a scar might be responsible for imperfect union, but he was convinced that the method of suture was of paramount importance, whether in clean or infected scars. An unpunctured, accurately apposed mucosa, and wide muscular union, as shown in the specimen, must be of importance. Furthermore, the absence of suture material projecting on the peritoneal surface removed or reduced a constant source of omental and intestinal adhesions.

The PRESIDENT stressed the necessity for accurate apposition of the edges of the scar. He said that his method of suture was similar to that of Professor Blair Bell, except that he did not use the mattress suture. A patient of his had had a temperature after an emergency Caesarean section. She did not report on her next pregnancy, but delivered herself normally. In the third pregnancy the scar ruptured.

Miss IVENS (Liverpool) said that she avoided the endometrium in sewing up these scars, and used two layers of catgut, the last layer taking a large portion of uterine muscle. She had had an opportunity of studying one of the scars five weeks after Caesarean section. The patient had fibroids, and since conditions were not suitable for hysterectomy at the time of the Caesarean section the uterus was removed five weeks later. The uterus showed that the scar was thicker than the rest of the uterine wall, and, microscopically, its track could be traced by a line of giant cells. Professor BLAIR BELL replied that a badly sewn wound was more likely to rupture afterwards, even in the absence of infection.

Fibromyoma Invaded by Adenocarcinoma.

Professor BLAIR BELL showed a specimen of a fibromyoma invaded by adenocarcinoma of unknown origin in a single woman, aged 47. Eight months previously she had had an operation in another city at which the appendix, right appendage, and a rectal polyp were removed. Since then she had had attacks of very severe pain in the right buttock, which shot down the leg; on examination a fibroid uterus was discovered. At operation a complete hysterectomy with left salpingo-oöphorectomy was performed, and a tumour, densely adherent to the rectum and uterus, was removed. Convalescence was uninterrupted, but the patient continued to complain of severe pain in the lower part of the back. Sigmoidoscopy, by Professor R. E. Kelly, revealed an annular constriction of the rectum, fixed to the left wall of the pelvis. The lumen, which admitted the little finger, was lined by normal mucosa. Professor Blair Bell had been informed that the patient later had a colostomy for intestinal obstruction, and eventually died of uraemia. Sections of the tumour adherent to the rectum and uterus showed it to be composed of ordinary fibromyomatous tissue. No malignant tissue was discovered in the area of attachment to the uterus or elsewhere. It was not possible on histological or other evidence to assert definitely that the malignant development in the fibromyoma was secondary to cancer of the rectum, but this appeared probable, and it was unfortunate that no section was made of the rectal polyp.

Mr. STACEY (Sheffield) said he had seen a case where adenocarcinoma developed in an area of the sigmoid which had been the seat of diverticulitis. Professor BLAIR BELL considered that the invasion of this tumour had probably been along the lines of the adhesions.

Ruptured Papillary Ovarian Tumour.

Professor BLAIR BELL showed a single woman, aged 35, who, eighteen months previously, had had the left ovary removed by Dr. Leith Murray; it was the seat of a growth similar to that he now described. It appeared malignant macroscopically, but on section was proved to be innocent. There were two pints of fluid evacuated from the abdomen due to rupture of the upper pole of the tumour previous to operation; the fluid was not bloodstained. In January, 1929, the patient was admitted to a medical ward with abdominal swelling, dyspnoea on exertion, swelling of the ankles, and loss of weight. One and a half pints of fluid were aspirated from the right pleural cavity, but there was no evidence of tuberculosis. A week afterwards eight pints of fluid were withdrawn from the abdomen by paracentesis. Eleven days later she was submitted to laparotomy under spinal anaesthesia, and two pints of thick, straw-coloured fluid were evacuated. The growth of the right ovary was slightly adherent posteriorly, and the uterus was displaced to the left. It was not removed, owing to the condition of the patient. There were bands running over the growth, which had the appearance of adherent intestine and omentum. The growth was also cystic in several places; its general appearance, however, was that of a friable, soft, solid, malignant tumour. Histologically it was a papillary adenoma.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the Aberdeen Medico-Chirurgical Society was held on April 4th, with the president, Professor Low, in the chair. A demonstration of clinical cases, with lantern illustrations, was given by members of the staff of the Royal Aberdeen Hospital for Sick Children. Dr. JOHN CRAIG showed a case of coeliac disease in a girl aged 6½, there being a history of diarrhoea for several years, with the passage of large loose pultaceous stools. She had been fed as an infant continuously on a proprietary food. The appearances of the case were classical—infantilism, large abdomen, thin flabby limbs, wasted buttocks, with the usual quaint introspective mentality and squeaky voice. Skiagrams showed many transverse striations of the ends of the long bones. Dr. Craig discussed the diagnosis and treatment, mentioned rickets and tetany as complications, and outlined the latest views on the etiology and pathology of the condition. He then submitted a case of Hirschsprung's disease in a girl aged 6, and showed a girl, aged 7, who had had repeated attacks of unexplained pyrexia. A mass of abdominal glands was discovered, and at operation these were seen to be caseo-purulent tuberculous glands. Removal resulted in the cessation of the febrile attacks. He exhibited skiagrams and a pathological specimen of a case of pyloric stenosis, and a unusual type of bone lesions in congenital syphilis—the pseudo-tuberculous type with caries and no attempt at repair. Dr. H. Ross SOUPER described the appearances and course of a case of acute suppurative frontal sinusitis in a girl aged 1[illegible]. There was marked swelling of both eyelids and bilateral pto[illegible] ptosis, and a fluctuating swelling was present in the mid-line of the forehead. A skiagram showed well-marked opacity of both frontal sinuses, with necrosis of the supraorbital ridge. At the operation pus was found superficial to the frontal bone, both frontal sinuses were filled with pus, and abscess cavities extended through the roof of both orbits. Part of the frontal bone was necrosed, and removal exposed the dura mater. Free drainage was established, but the patient died next day. [illegible] haemolytic staphylococcus was isolated from the pus. Dr. Souper also described a case of lateral and cavernous sinus thrombosis in a boy, aged 3, who, on admission, had a temperature of 100.2° F. and slight left otorrhoea, but no definite external signs of mastoiditis. Two days later oedema of the left eyelid appeared, followed by oedema of the right eyelid on the next day. The temperature rose to 103°, and a polymorphonuclear leucocytosis of 43,000 was present. At operation

necrosis of the mastoid cells was found; the lateral sinus was seen to be covered with granulations, and contained a clot, which was removed. The patient received antistreptococcal serum, but died the following day. Dr. Souper discussed a series of 22 cases of tuberculous mastoiditis in children. He said that the condition occurred between the first and third years of life, was insidious in onset, and the facial nerve was often involved. The ear discharge was curdy and flaky, and multiple perforations were often present; early glandular involvement occurred, and the pre-auricular glands were especially implicated. Dr. J. F. CHRISTIE illustrated with lantern slides a case of ecthyma which, he said, was really a deeper form of streptococcal impetigo, although sometimes a deep tuberculous focus was concerned in the etiology. The children were usually in poor condition, and the buttocks, thighs, and legs were most commonly affected. The best application was a 1 per cent. solution of silver nitrate or 1 in 2,000 solution of mercuric chloride. In the present instance the child made a good recovery, but returned to hospital three weeks later with broncho-pneumonia. Six weeks after convalescence the patient was readmitted and died of generalized tuberculosis. Dr. Christie also described a case of pemphigus vulgaris in a boy, aged 3, who had suffered from chicken-pox three months previously. Typical bullae appeared on the arms, backs of the hands, genitals, and adjacent parts of the thighs. The bullae came out in crops without much rise in temperature, and with no itching. A polymorphonuclear leucocytosis was present with 7 per cent. eosinophils. Condy baths were prescribed, and an ointment containing hydrarg. ammon. and ichthyol was applied. Increasing drop doses of Fowler's solution were given by the mouth. There was no improvement after a month, and quinine sulphate was then given. Later, on withdrawing serum from what appeared a sterile bulla, an almost pure culture of a haemolytic streptococcus was found. Antistreptococcal serum was then injected, a total of five doses being given at seven days' interval. Bullae still continued to form, with slight rises in temperature, but at the end of five weeks the child was considerably better, and left the hospital with no signs of any skin affection. Dr. WILLIAM BROWN showed lantern slides of two cases of erythroedema polyneuritis ("pink disease"), illustrating the change in temperament and expression: the swelling of the face and the high colour of cheeks and nose; the presence of stomatitis; the desquamation of hands and feet, with tenderness; and the characteristic attitude in bed; with contrast slides of the children during the attack and on recovery. The two chief indications of the disease were the look of "misery" and the colour of the hands and feet. Both patients were admitted with a history of change of temperament and of depraved appetite, sweating, and redness and coldness of the extremities. One child was in hospital for four months, and the other for two months. Both were treated with a diet rich in vitamin B, in addition to general tonic treatment. Marmite was given in large doses. One patient improved rapidly on receiving ultra-violet rays: calcium was given to both. Mention was made of the similarity, in some respects, between this disease and beri-beri and pellagra, especially the last. Professor Low thanked the speakers on behalf of the society, and expressed special appreciation of the excellent series of lantern slides with which Dr. William Brown had illustrated the cases described.

AT a meeting of the Society for the Study of Inebriety on April 9th, Dr. J. D. ROLLESTON opened a discussion on alcohol in therapeutics. After a brief historical introduction, in which he showed that from the earliest times the medical profession had been by no mean unanimous on the subject, Dr. Rolleston said that a remarkable decline had taken place within the last thirty years in the therapeutic use of alcohol. This was best illustrated by the fall in the alcohol bill in various hospitals; it was also exemplified by the practice of individual physicians, and the small place which alcohol now occupied in textbooks of medicine. The low esteem in which alcohol was held as a therapeutic agent in the United States was shown by the fact that only a minority of practitioners applied for a licence in those States in which the right to prescribe alcohol was granted, and some of these were said to use it for illicit purposes. Dr. Rolleston added that the conditions in which alcohol was still chiefly employed were pneumonia, enteric fever, diphtheria and other acute infections, diabetes, heart disease, tuberculosis, senility, and inoperable cancer, but it did not appear to be indispensable in any of them. The experience at the Western Hospital, of which he was medical superintendent, had shown that in an annual population of 5,000 patients the consumption of alcohol could be almost abolished without any injurious effects. The factors chiefly responsible for the undeserved esteem which alcohol still enjoyed as a therapeutic agent appeared to be tradition rather than scientific evidence, extra-medical influences, and personal considerations.
